

Intellectual Property Regimes and Firm Structure*

February 2018

Abstract

We use The Patents (Amendment) Act, 2002 in India as a quasi-natural experiment to identify the causal effect of higher incentives for innovation on firm organizational features. We find that stronger intellectual property (IP) protection has a sharper impact on technologically advanced firms, i.e., firms that were a-priori above the industry median in terms of technology adoption. While there is an overall increase in managers' share of compensation, this increase is about 1.6-1.7% more for high-tech firms. This difference can be attributed to a larger increase in performance pay for high-tech firms. The reform also leads to a significant increase in number of managerial layers and number of divisions for high-tech firms relative to low-tech firms, but only the latter effect is correlated with the differential change in managerial compensation. Broadly, we demonstrate that stronger IP protection leads to an increase in both within-firm and between-firm wage inequality, with more robust evidence for between-firm inequality.

1 Introduction

There is a growing literature studying how firm organization is affected by different kinds of macroeconomic shocks – drop in tariffs due to trade agreements (Guadalupe and Wulf, 2010), export market participation (Caliendo and Rossi-Hansberg, 2012; Keller and Olney, 2017; Caliendo et al., 2017), input-trade liberalization (Chakraborty and Raveh, 2018), etc. In this paper, we study how the imposition of stronger Intellectual Property Rights (IPR) affects various dimensions of the structure of firms. We analyze an exogenous change in the Indian patents regime brought about by a landmark legislation, the **The Patents (Amendment) Act, 2002**. While Indian firms could only patent new production processes, this act allowed firms to claim patents for new products. This change substantially strengthened property rights over innovation and significantly raised firms’ incentive to innovate. We study how a large cross section of Indian manufacturing firms responded to this Act in terms of changes in organizational structure. To the best of our knowledge, we believe that our work is the first to look at how a change in IPR affects firm structure as well as wage inequality.¹

Our aim is to establish a causal link between firm structure and innovation, and examine exactly what features do firms believe are the most conducive to innovation performance. A large body of evidence, both in management and economics, demonstrates that organizational structure is a crucial determinant of a firm’s ability to innovate.² However, as Azoulay and Lerner (2013) point out in their detailed survey on the topic, the existing empirical literature largely focuses on the correlation between organizational structure and innovation performance and fails to credibly identify causal channels.³ A major contribution of our work is to identify a suitable quasi-natural experiment which is a change in intellectual property rights (IPR) regime that enhances firms’ future incentives to innovate. We rely on the simple fact that firms react to these incentives and modify their organizational structure based on their capabilities. This allows us to interpret

¹Kamal and Lovely (2013), which looks at the effect of China’s WTO accession on formation of joint ventures, is the only other paper we found that relates IPR regime to firm structure.

²In particular, various indicators of innovation inputs or performance have been shown to be correlated with different aspects of firm structure, e.g., firm size (Schumpeter, 1942; Cohen and Levin, 1989) compensation schemes (Manso, 2011; Amabile, 1993 and 1996; Teece, 1994), structure of employee contracts (Azoulay et al., 2011), product scope (Brugelman, 1984), level of vertical integration (Azoulay, 2004), degree of centralization (Argyres and Silverman, 2004), number of layers or more generally, organizational complexity (Teece, 1994; Stein, 2002; Berger et al., 2005).

³“An essential difficulty facing large-sample empirical research has been an inability to distinguish between association and causation, and, in some cases, a failure even to think carefully about this distinction.” – Azoulay and Lerner (2013), Handbook of Organizational Economics, pp 576.

the observed firm-level responses to the **The Patents (Amendment) Act, 2002** as those that enhance innovation potential.

We analyze firms' response to this exogenous change in IPR regime in three different dimensions of organizational structure: (i) relative demand for managers vis-a-vis non-managers measured as share of compensation, (ii) extent of performance pay for managers, and (iii) organizational design, i.e., number of management layers and number of divisions. We find a sharp heterogeneity in firm's response to the IPR shock: the firms that were a-priori technologically advanced at the time of the reform had significantly larger increase in each of these three dimensions relative to the technologically backward firms. An important implication of our finding is that imposition of a stronger IP regime increases wage inequality both within-firms and between-firms, with the latter effect being significantly stronger.

India's patent policy started to shift towards greater protection of intellectual property rights as a result of the emergence of Trade Related Intellectual Property Rights (TRIPs, hereafter) in the WTO (after 1995). India got a 10-year transition period to implement a TRIPs-complaint IPR regime, but during this period there were several inconclusive rounds of discussion in the parliament due to opposition from various sections of the political establishment (Reddy and Chandrashekar, 2017). Eventually, in June 2002, the Indian parliament passed the second amendment to the 1970 Act known as **The Patents (Amendment) Act, 2002** (Act 38 of 2002).⁴ It proposed a new definition of the term 'invention' which changed patent rights from process to product innovations, increased the term of patents from 14 to 20 years, brought all fields of technology under the ambit of patents and streamlined the process of patent grant. This act ended the earlier policy uncertainty and provided the necessary impetus to firms to make the fixed investments in new technology to harness the benefits of the new IP regime. **Figure 1** demonstrates a sharp increase in investments in technology adoption by a large sample of Indian manufacturing firms.

By conferring monopoly rights over new products, the Act significantly raised the payoff to innovation. Innovation involves a whole range of activities that are intensive in managerial talent: research, conceptualization and development of new products, branding and marketing the product and so on. Innovation presents firms with more complex problems, and this raises the value of managers as problem-solvers (Garicano, 2000). Therefore, under the new IPR regime, one would

⁴This Act came into force on 20th May 2003 with the introduction of the new Patent Rules, 2003 by replacing the earlier Patents Rules, 1972.

expect relative returns to managerial skills as well as demand for managers to increase across all firms. However, the firms that had a-priori higher investments in technology had comparatively larger gains from innovation either because they were more likely to win patent races or because of reduced marginal cost of additional investment. The increase in relative returns to managerial inputs would be higher in such firms, and they would also have stronger incentives to make complementary changes in their organizational structure.⁵ In order to see whether these hypotheses are true, we use The Patents (Amendment) Act, 2002 as the quasi-natural experiment to investigate the effects of the change in IPR regime in terms of demand for managers and firm structure.

The empirical literature on organizational structure of firms is scarce due to limited data availability. We employ a firm level panel dataset from the PROWESS database provided by the Centre for Monitoring of the Indian Economy (CMIE). The dataset contains direct measures of spending on several dimensions of technology adoption, namely R&D expenditure and royalty payments for technology transfer, allowing us to build a comprehensive and accurate measure of investment in technology. It also reports detailed labour compensation, divided into managerial and non-managerial, with the former divided into several management layers (Chakraborty and Raveh, 2018). In addition, the dataset provides exports, imports, capital employed and other important firm and industry characteristics. The panel format of the data enables us to have a dynamic specification in which technological investments and other firm decisions can potentially affect demand for managers.

We begin our analysis by dividing firms into two groups, ‘high-tech’ and ‘low-tech’, following Branstetter et al. (2006) and applying to our case. We classify a firm as high-tech, if a firm’s average expenditure on R&D and technology transfer between 1990-2001 is greater than the median in the corresponding industry. By doing so, we create a ‘treatment’ and ‘control’ group where the control group is the low-tech firms. There are two empirical challenges in establishing a causal relationship between change in IP regimes and relative demand for managers complemented with technology adoption: (a) unobservable characteristics of a firm might drive both the demand for managers and investment in technology posing challenges to identification; and (b) a higher share of managers may itself affect the likelihood of undertaking new investments in technology, (i.e., the reverse

⁵Aghion et al. (2017) finds that a positive export shock raises innovation more for more productive firms. The channel, in their case, is that more productive firms are less affected more by competition from domestic firms in the destination country. We have a similar channel where innovative effort is more likely to be successful for more productive firms.

causality problem). We use a quasi-natural experiment in terms of patent policy change to tackle the former, whereas for the latter, we use a diff-in-diff approach which exploits the timing of firm level decisions to pin down the direction of causality. The diff-in-diff approach also isolates the effect of the change in the innovation policy on organization from the effect of globalization and other activities that might be complementary to policy change. We expect that a stronger patent policy would induce a higher demand for managers in the a-priori high-tech firms than the low-tech firms (given the complementarity between technological investments and managerial inputs).

Table 1 compares high-tech and low-tech firms before and after the 2002 IP reform on various characteristics, such as technology adoption, managerial compensation, capital employed, trade (exports and imports) and sales. We calculate the mean share of these observable characteristics over the gross value-added of a firm. We see that in the pre-reform period, the high-tech and low-tech firms differ significantly in terms of technology adoption but not on other major observable characteristics. This points out that differences between ‘treated’ and ‘control’ group of firms arises after the reform.

Figure 2 plots technology adoption for our sample of Indian firms for the period 1990-2006 by dividing into high-tech and low-tech firms. The figure clearly shows similar trend for high-tech and low-tech firms before the adoption of the patent reform but quite the opposite after. The technology adoption expenditure for the high-tech firms nearly doubled between 2002 and 2006, whereas for low-tech firms it shows a decline. **Figure 3** plots the average share of managerial compensation in total compensation for the entire sample of firms and **Figure 4** does the same for high-tech and low-tech firms separately. We find that while there was an increasing trend in managers’ share of compensation in both types of firms, the increase in the high-tech group was approximately double that of the low-tech firms. These two diagrams suggest a possible association between patent reform, technology adoption and demand for managers and paves the way to provide causal inferences.

In our analysis, we emphasize three important questions: (a) how imposition of stronger patent rights impacts the demand for different kinds of workers (in our case managers and non-managers) differently; (b) how this change in relative demand is reflected between- and within-firms; and (c) how it impacts the organizational design of a firm.

Our paper has three sets of results. The first part estimates the reduced form effect of change in innovation policy complemented with technological adoption of firms on the relative demand for

managers. We find a remarkably persistent statistically significant and economically meaningful positive effect of The Patents (Amendment) Act, 2002 on the relative demand for managers, both at the intensive and extensive margin. Our benchmark estimations indicate that The Patents (Amendment) Act, 2002 led to an increase in the share of managerial compensation of the high-tech vis-à-vis the low-tech firms by around 1.6-1.7%. The effect is robust to various controls, specifications, estimation techniques and time-periods.

Our second result points out that technologically-advanced firms use sharper incentives to motivate managers as a result of the reform. There is considerable debate in the literature about how and whether incentives motivate innovation and creativity (Holmstrom, 1989). Earlier work (e.g., Teece, 1994; Amabile, 1996) suggests that high-powered incentives stifle creativity and innovation, whereas current literature (e.g., Manso, 2011; Ederer and Manso, 2011; Azoulay et al., 2011) focus on forms of long-term incentive mechanisms that motivate innovation. In our case, we find that increased incentive pay is necessitated by the particular way that IP reform affects innovation incentives. A strong IP regime induces patent races, which reward not just the innovation but also the time to innovate. Motivating quicker innovation requires aggressive managerial incentives.

Lastly, we find that the span of control of managers as proxied by the number of product varieties increases more for technologically advanced firms. We interpret this as evidence of establishment of new divisions due to new product development. Moreover, the differential increase in share of managerial compensation is highly correlated with such horizontal expansion.⁶ This result is consistent with the idea that decentralized firm structure is more suitable to innovation (Caroli and Van Reenen, 2001).

Our findings suggests that stronger patent rights leads to an increase in inequality of two different kinds: (i) the technological gap between high-tech and low-tech firms increases; and (ii) both within- and between- firm wage inequality increases. Two papers point out such increase in gap between different groups as a result of different kind of shocks. Aghion et al. (2005) while investigating the relationship between competition and innovation highlights that the average technological distance between the technological-leaders and -laggards increases with competition. In a slightly different context, Galor and Moav (2000) points out that an increase in the rate of

⁶There is a debate about whether vertical hierarchies are conducive to innovation. While some papers (e.g., Teece, 1994; Caroli and Van Reenen; 2001) advocate that layering and decentralization are conducive to innovation, others (e.g., Argyres and Silverman, 2004; Lerner and Wulf, 2007) suggest the opposite. While we find a significant increase in vertical layers due to the reform, there is no evidence that this vertical expansion contributes to the increase in the share of managerial income.

technological progress raises the return to ability and simultaneously generates an increase in wage inequality between and within groups of skilled and unskilled workers (Kline et al., 2017).

There are at least two channels through which innovation policy affects firm organization through technology adoption. First, a stronger patent protection lead firms to invest in exploring new avenues like product development, research activities, marketing activities for brand development, etc. all of which lead to horizontal expansion of a firm (Teece, 1986, 1994). Second, existing processes are also pushed closer to the technological frontier through use of more R&D expenditure, technology transfer, import of capital goods, etc. Both these effects increase the demand for managers and result in technological deepening. Notice that due to the inherent complementarities in technological advancement, both these effects are stronger in firms that are already technologically superior. As a result, we observe that a stronger patent regime leads to an increase in the inequality across firms in technology intensiveness as well as share of managerial compensation in total compensation.

The paper contributes to several strands of literature. We directly add to the literature on how different kinds of shocks can induce changes in firm structure e.g., technology adoption (Bresnahan et al., 2000), communication technology (Garicano, 2000, Garicano and Heaton, 2010), globalization (Guadalupe and Wulf, 2010; Spanos, 2017; Chakraborty and Raveh, 2018), etc. In our case, this exogenous shock comes from an exogenous change in innovation policy. A significant portion of literature argues that some kind of technological adoption is complement to organizational change and raises the employment shares or relative demand for skilled workers over unskilled workers (Caroli and Van Reenen, 2001) or managers over workers (Lee and Shin, 2017). However, as mentioned above all the studies establishes a correlation, while we show causal relation between innovation and organizational change.

The paper also relates to the growing literature investigating the impact of innovation policy on wage inequality. Boler (2015) uses a R&D tax credit scheme in Norway to demonstrate that innovation significantly increases the demand for skilled workers and the increase in demand is due to a change in within-firm skill-biased productivity growth. While our results are similar, we find that between-firm inequality plays a larger role than within-firm inequality in explaining the increase in relative demand for managers. Moreover, we complement this literature by analyzing how firm organization changes because of a shift in the innovation policy. Kline et al. (2017) analyzes how patent applications can induce inequality in worker compensation among U.S. firms.

In a similar context, Aghion et al. (2015) uses data on US states to show that top income inequality is (at least partly) driven by innovation. In a different context, Song et al. (2016) show that a large majority of the overall inequality is driven by increasing dispersion between, not within, firms which is similar to our finding.

Third, our finding that a change in IPR regime works through the capital-skill complementarity channel has a parallel in the literature on the trade-induced skill-biased technical change (Acemoglu, 2003; Michaels et al., 2014; Autor et al., 2017), particularly in developing economies (Amiti and Cameron, 2012; Raveh and Reshef, 2016; Maloney and Molina, 2016). In a similar context, Ugur and Mitra (2017) maps the qualitative and empirical evidences to report that the effect of technology adoption on employment is skill-biased and more likely to be observed when technology adoption favours product as opposed to process innovation. Vashisht (2017) examines the impact of technology on employment and skill demand for the Indian manufacturing sector and demonstrates that adoption of new technology has increased the demand for high skilled workers. This finding is consistent with ours, as we show that higher technology adoption leads to demand for more managers.

Fourth, we contribute to the debate on whether sharp incentives lead to greater innovative output. Holmstrom (1989) identifies the difficulties in motivating innovative effort. Teece (1994) and Amabile (1996) hold that sharp incentives may be inimical to innovation. Empirical work by Lerner and Wulf (2007) and Kline et al. (2017) finds that innovation is associated with long term (rather than short term) incentives. On the contrary, we uncover strong evidence that technologically advanced firms provide sharper incentives as a result of the IPR shock. Such incentives are provided to the middle level managers (i.e., divisional heads and functional heads) who are typically responsible for new product development. Moreover, we find that such incentives are associated with higher innovative output in at least two senses: the high-tech firms introduce more product lines as well as file more patent claims due to the IPR shock.

Finally, the paper relates to the effect of IPR reform on innovative activities of countries, industries, firms. The effect of an IPR reform on innovation performance has been addressed at multiple levels: country (Park and Lippoldt, 2004; Chen and Puttitanun, 2005; Branstetter et al., 2006; Qian, 2007), industry-firm (Sakakibara and Branstetter, 2001; Allred and Park, 2007; Yang and Maskus, 2009; Lo, 2011). We extend and complement this literature by looking at the effect of an IPR reform on within- and between-firm dimensions of management and organization. In

addition, it also contributes to the literature on the effect of the specific 2002 IPR reform in India.

The paper is organized as follows. The next section lays out the details of the reform. We provide details about the data, in Section 3. The empirical strategy and exogeneity of the reform is discussed in Section 4. In Section 5, we report our results, showing the effect of higher incentives to innovation on demand for managers through higher technology adoption and how does it simultaneously affects other aspects of firm organization. We discuss the likely channels through which our effects work in Section 6. The last section concludes.

2 Institutional Background

The pre-1990s intellectual property regime in India was governed by the The Indian Patent Act, 1970, which was aimed at preventing foreign monopolies.⁷ According to the Act, only process and not product innovations were granted patents. The term for patents was fixed at 14 years (and only 5-7 years in chemicals and drugs) while the international standard was 20 years. Several areas were excluded from patents, and the government could use patented inventions to prevent scarcity. Such a system allowed domestic firms to imitate foreign products with a slightly different process, thus expropriating value from investment in product innovation made by foreign firms. The 1970 Patent Act soon started facing international resistance as discussions on free trade started getting linked to IPR.

In 1991, India ran into its much-discussed balance-of-payments (BOP) crisis and turned to International Monetary Fund (IMF) for assistance. The IMF conditioned its assistance on the implementation of a major adjustment program that included several liberalization steps and becoming a member of the World Trade Organization (WTO). In 1994, India signed the Marrakesh Agreement and agreed to be bound by TRIPs. It enabled India to get a 10-year moratorium period (1995-2005) to transition to a stronger, TRIPs-compliant IPR regime which would respect product patents (for details see Chaudhuri, 2005). This transition had several hiccups with uncertainty around the implementation of the new regime. As we explain below, the uncertainty cleared only

⁷The Patent Act of 1970 was partly based on the recommendations of Patent Enquiry Committee (1948-50) and the Ayyangar Committee (1957-59), which made two major observations: (i) the Indian patent system has failed to stimulate and encourage the development and exploitation of new inventions for industrial purposes in the country; and (ii) foreign patentees were acquiring patents not in the interests of the domestic economy but with the objective of protecting an export market from competition of rival manufacturers. The reports also concluded that the foreigners held 80-90% of the patents in India and were exploiting the system to achieve monopolistic control of the market (Ramanna, 2002).

by 2002, and this provides us the structural break that we exploit in our study.

India's initial transition started with the failed The Patents (Amendment) Ordinance, 1994 which was tabled by a weak coalition government, amending The Indian Patent Act, 1970. It allowed for a 'mailbox' provision through which firms could file product patent applications which would be reviewed on a priority basis as and when India amends its patent laws to comply with TRIPs. However, uncertainty remained about the exact time frame of this transition. Simultaneously, The Patents (Amendment) Bill, 1995 was introduced in the Parliament to enforce the ordinance.⁸ As per Indian law, a bill must be passed by both houses of the parliament. While the Upper House passed it, the Indian parliament was dissolved due to ideological differences between members of the ruling coalition once the bill was in the lower house of the parliament. The Patents (Amendment) Bill, 1995 automatically lapsed leaving the uncertainty around IPR transition alive.

The United States filed a complaint against India to the Dispute Settlement Board (DSB) of the WTO in 1996 for failing to abide by the TRIPs.⁹ India lost this case, despite an appeal, with the U.S. further bolstered by a European Community complaint. India then negotiated with the U.S. to amend its patent law by April 1999.¹⁰ Finally, in order to honour this commitment made to the DSB, India implemented The Patents (Amendment) Act, 1999 despite civil society concerns. This amended Act had the provision for filing of applications for product patents in the areas of drugs, pharmaceuticals and agrochemicals, though the applications were only to be reviewed after 31st December, 2004.¹¹ However, this Act came as a compromise in what was still an uncertain environment around patent policy and was basically a post factum of the failed Patent (Amendment) Bill, 1995. It failed to encourage much innovation.

Throughout the nineties, patent policy in India was subject to a political tug-of-war. While a large section of the INC (Indian National Congress, the ruling party during the first half of the decade) had been sympathetic to liberal patent laws, there was stiff resistance from the opposition

⁸In Indian constitutional law, ordinances are valid for only six months from the day of promulgation, or six weeks from the day Indian Parliament reconvenes after the ordinance is promulgated.

¹⁰Dispute Settlement Body, India - Patent Protection for Pharmaceutical and Agricultural Chemical Products - Reasonable period of time for implementation of the DSB's recommendations, WT/DSB/M/45 (Jun. 10, 1998), at 16.

¹¹Further, the applicants could be allowed Exclusive Marketing Rights to sell or distribute these products in India, but subject to fulfilment of certain conditions.

as well as parts of INC. In April 1993, a parliamentary committee tasked to study the draft proposal by Arthur Dunkel on Uruguay round of GATT documented the strong unwillingness of India to comply with TRIPs,¹² although its recommendations were rejected by the ordinance of 1994. The BJP (Bharatiya Janata Party), after coming to power in 1998, abandoned its opposition and adopted a pro-patent position. By the turn of the millennium, a majority within both the BJP and the INC favoured a more liberal patent policy.¹³ By this time, a domestic constituency had also emerged in support of the patent reform. The support occurred at different levels: first, the impact of liberal ideas regarding economic reforms slowly led to a more westernized notion of IPR; second, by this time a more ‘modern’, professionally managed and technologically advanced segment of industry had developed in India; third, top Indian research and scientific institutes (e.g., Council of Scientific and Industrial Research, CSIR) felt that they could benefit from patents rather than publications (Ramanna; 2002; Choudhury and Khanna, 2014).¹⁴

Given this background, The Patents (Amendment) Act, 2002 laid the foundation and provided the necessary impetus to change the intellectual property regime in India. According to the Controller General of Patents, Design and Trademarks, Govt. of India, The Patents (Amendment) Act, 2002,¹⁵ replaced the earlier patent rules implemented by the 1970 Act.¹⁶ This legislation proposed a new definition of the term “invention”, introduced product patents in all fields of technology, increased the term of patents from 14 to 20 years (complying with TRIPs), limited the scope for the government to use patented inventions. This Act really broadened the scope for the implementation of the TRIPs complying IPR regime that India was committed to adopting.¹⁷ Three years later India was able to push this second legislation further with the addition of 3(d), the compulsory

¹⁴ASSOCHAM (Associated Chambers of Commerce and Industry) also gave a written submission to the Committee on the need for phased introduction of product patents in India and pointed out that it was of the view that to attract increasing flow of Foreign Direct Investment, it is important for India to strengthen the patent system. This will ensure higher interaction in R&D as well as flow of foreign capital.

¹⁵This act came into force on 20th May, 2003

¹⁶<http://www.ipindia.nic.in/history-of-indian-patent-system.htm>

¹⁷It additionally introduced the “Bolar” exception, inspired by US law exempting manufacturers from infringement if they develop products, conduct research and submit test data for regulatory purposes. A joint parliamentary committee was constituted which submitted a report to the lower house of the Indian parliament; while its research was thorough, political circumstances ensured that the 2002 bill faced lesser difficulties than the earlier legislation and thus The Patents (Amendment) Act, 2002 was enacted.

licensing provision, and implemented The Patents (Amendment) Act, 2005 to comply with all the provisions of TRIPs (see Chatterjee et al., 2015 for more details on 3(d)).

Our detailed discussion of the events suggests that there was a significant amount of uncertainty in transition to a stronger IPR regime, which essentially cleared up with The Patents (Amendment) Act, 2002. We utilize this Act as a quasi-natural experiment to understand how the change in the intellectual property rights regime affects a firm’s structure.. We conduct a variety of exogeneity checks (explained in detail in Section 4.1) to ensure that we address any confounding impact of potential ex-ante industry- or firm-level changes that may have influenced the 2002 IPR reform.

3 Dataset

We exploit a dataset of Indian manufacturing firms drawn from the PROWESS database, constructed by the Centre for Monitoring the Indian Economy (CMIE). The dataset has previously been used by Khandelwal and Topalova (2011), Ahsan and Mitra (2014) and Chakraborty and Raveh (2018), among others. The dataset accounts for more than 70% of the economic activity in the organized industrial sector, and 75% (95%) of corporate (excise duty) taxes collected by the Indian Government (Goldberg et al., 2010). All variables are measured in Millions of Indian Rupees (INR), deflated to 2005 using the industry-specific Wholesale Price Index, and are outlined in **Appendix A** (Data). **Table 2** presents descriptive statistics for all variables.

The database contains information on approximately 27,400 publicly listed companies, all within the organized sector, of which almost 11,500 are in the manufacturing sector.¹⁸ It reports direct measures on a vast array of firm level characteristics including sales, exports, imports, R&D expenditures, technology transfer, production factors employed, gross value added, assets, ownership, and others. The dataset covers both large and small enterprises; data for the former types is collected from balance sheets, whereas that for the latter ones is based on CMIE’s periodic surveys of smaller companies.

PROWESS presents several features that makes it particularly appealing for the purposes of our study as compared to other available sources, such as the Indian **Annual Survey of Industries** (ASI), for instance. First, unlike other sources, the PROWESS data is in effect a panel of firms,

¹⁸While placed according to the 4-digit 2008 National Industrial Classification (NIC) level, firms are reclassified to the 2004 level to facilitate matching with the industry-level characteristics. Hence, all industry-level categorization made throughout the paper are based on the 2004 NIC classification.

enabling us to study their behavior over time; specifically, the (unbalanced) sample covers 108 (4-digit NIC) manufacturing industries that belongs to 22 (2-digit NIC) larger ones,¹⁹ over the period of 1990-2006.

Second, the feature of the data set upon which our study is based, is that it disaggregates compensation data by managers and non-managers, with a further disaggregation of compensation to wages and bonuses. Additionally, the managers are divided into two groups: directors and executives.²⁰ The non-managers are defined as those who do not manage other employees. Directors are defined as managers without executive powers, as opposed to executives who do possess such responsibilities. Executives include, for instance, the CEO, CFO, and Chairman, whereas Directors may include positions such as Divisional Managers.²¹ In effect, we consider directors to be middle management, whereas executives are the top management.

A key related issue is regarding the accuracy and consistency of the data. Chakraborty and Raveh (2018) compares the compensation data for 20 randomly selected firms (representing both relatively large and small ones) from PROWESS with that of those reported in the annual reports and finds that the correlation is higher than 0.99. We implicitly assume that there is consistency in the definition of managers across firms.²²

The data set provides a large variation across firms and industries in the compensation of managers compared to non-managers, which enables us to better understand how they react to IPR reform. For instance, the average share of managerial compensation in total labour compensation

¹⁹In terms of composition, approximately 20% of the firms in the dataset are registered under the Chemical and Pharmaceutical industries, followed by Food Products and Beverages (13.74%), Textiles (10.99%) and Basic Metals (10.46%).

²⁰It may well be that there are more layers in a given firm, but the nature and scope of the data does not enable us to empirically observe these sub-layers, capping the analysis at three hierarchical layers. Caliendo et al. (2015) uses data for French manufacturing firms to classify each firm by four vertical layers according to occupational tasks. Cruz et al. (2018), on the other hand, uses data for Brazilian firms to see whether capacity building programs impacts firm organization. They follow Caliendo et al. (2015) to segregate the firms into five hierarchical layers. However, both of these studies classify CEOs and senior managers into two different hierarchical levels, where we have combined them into one with executive powers within a firm. In addition, Cruz et al. (2018) divides the non-managers between clerks and services as well.

²¹For example, a firm 'Jaipur Polyspin Ltd.', Mr. V. K Singhal has been designated as 'Manager (Production)' and Mr. S. L. Dhanuka as 'Chairperson and Managing Director'. In case of 'Unimin India Ltd.' has Mr. M. G. Karkhanis as 'Vice-President (Marketing)', and Mr. J. B. S. Bakshi as 'Chairperson and Managing Director'. We note that the names of the managers belonging to the middle management are more sparsely reported than those in the top management. However, this is not the case with the compensation data.

²²There is scope for some subjective interpretation of this distinction by firms, when providing data. However, all firms included in the analysis are listed in the Mumbai Stock Exchange, and hence are subject to the same corporate governance and reporting regulations including the said definitions, which mitigates this concern to a large extent. Moreover, our results on managers as a single group do not get affected by such issues.

across 2-digit industries for the period of 1990-2006 goes from a low of approximately 1.5% to a high of around 9% (Chakraborty and Raveh, 2018). The variation is also observed when measuring changes (in managerial compensation) over time; averaging annual changes over the same period, we observe that while in some industries the average annual rate of change is around 10%, in others it can get as high as 200%. Such variation will be more prominent when the data translates to the firm level.

4 Empirical Strategy

Higher incentives to innovation induce firms to change their internal structure to maximize innovation potential, and this change is more pronounced for more technologically advanced firms. To assess such effects, we use The Patents (Amendment) Act, 2002 as an instrument for innovation to analyze its effect on the share of managerial compensation in total labour compensation for manufacturing firms in India. We use a difference-in-differences approach following Branstetter et al. (2006, 2011) controlling for other firm and industry level characteristics and other simultaneous policy changes that might affect the outcome of interest using the following specification:

$$\left(\frac{Mcomp}{Tcomp}\right)_{it} = \alpha_i + \alpha_t + \alpha_{jt} + \beta_1(IPR_{02} \times HighTech_i) + \beta_2 IPR_{02} + \beta_3 X_{ijt} + firmcontrols + \epsilon_{it} \quad (1)$$

where, i indexes an individual firm, j the firm's industry group, and t the year. $Mcomp$ denotes the total managerial compensation, whereas $Tcomp$ is the total labour compensation of a firm. So, the dependent variable measures the share of managerial compensation in total labour compensation of a firm. IPR_{02} is the post-IPR reform dummy variable, which takes a value of 1 for years on and following the imposition of The Patent (Amendments) Act, 2002. In particular, IPR_{02} takes 1 for the years 2002-2006.

An intellectual property rights reform raises the incentives to invest both in R&D and technology transfer. On the other hand, managerial skill is complement to technological inputs. Therefore, the firms that already have higher level of technology at the time of the reform, would demand more managers than those which are technologically less advanced. Acemoglu et al. (2006) argues that for countries which are closer to the technology frontier, selection of high-skilled managers becomes crucial as managerial skill is important for innovation. To study whether such is the case at the

firm-level, i.e., whether a change in patent regime affects firms’ demand for managers differentially, we divide the firms into two groups based on their investment in technology adoption before the reform. Firms that over the years before the reform (1990-2001) average greater than the median technology adoption (sum of R&D expenditure and royalty payment for technical know-how) of the industry to which it belongs, are defined as ‘high-tech’ firms or ‘treated’ group in our estimation. We assign these firms a high technology use dummy, *HighTech*, equals to 1. For the rest of the firms, *HighTech* equals 0, which serves as ‘control’ group in our estimations.²³

Therefore, our key variable of interest is the interaction term $IPR_{02} \times HighTech$ (or its coefficient β_1). It measures the differential response of the high-tech and low-tech firms due to the IPR shock in terms of demand for managers. In other words, β_1 measures between-firm inequality in terms of demand for managerial workers. On the other hand, IPR_{02} estimates the direct effect of the IPR reform on the demand for managers. Alternatively, it measures the within-firm changes in the share of managerial compensation on total labour compensation.

X_{ijt} is a vector of firm and industry characteristics which are likely to impact a firm’s managerial compensation. For example, following Chakraborty and Raveh (2018), we use both input and output tariffs at the industry-level to control for trade reforms initiated by the Govt. of India during the 1990s. We also specifically control for product market competition effect (both for domestic and export market), skill-intensity, management technology, IT expenditure, labour-regulation, productivity, etc. We also include three firm-level controls (*firmcontrols*) in all our specifications: age of a firm (older firms may have a more established structure and culture; controlling for age would take care of the potential differences in the flexibility of undertaking organizational reforms), amount of capital employed as a share of total gross value-added (higher capital intensity may also raise the demand for managers significantly) and assets (larger firms may have greater management needs). We use assets and capital intensity in $(t - 1)$ period. α_i and α_t are time-invariant firm and year fixed effects, respectively.

While estimating the above equation, we carefully control for other simultaneous reforms, such as delicensing of industries, tax incentives for R&D, The Competition Act, 2002, corporate gover-

²³While it is true that this is not a perfect control group that we could use in the estimations, given the nature of the reform, it is difficult to find a group of firms, which is exogenous to the change in intellectual property regime. Given the circumstances, this is the best we could use as all other sectors are also simultaneously impacted by other reforms (e.g., trade reforms). Using any other sector, say agriculture, would have been more exogenous to the reform, but the behavioural pattern of the agricultural sector is completely different from that of services and may bias the results in a different manner.

nance reforms²⁴, etc. that may affect the share of managerial compensation in a firm. Those, if not controlled for can bias our outcomes. To control for these unobserved policy changes (or any other change in the economic environment affecting all firms), we use α_{jt} – industry-year trends. We interact a firm’s industrial classification at NIC 5-digit level (most disaggregated level of industrial classification) with year trends to control for other simultaneous policy reforms that may affect our dependent variable. We also replace the industry-year trends with industry-year fixed effects at various aggregate (industrial classification) levels, but the results do not change.

However, one should still be careful in interpreting the basic estimates as conclusive evidence of the causal effect of the IPR reform on the differential demand for managers between high-tech and low-tech firms because of the following two reasons: (a) omitted variable bias; and (b) reverse causality. We address the former by sequentially adding various firm and industry characteristics and its interaction with the *HighTech* dummy to our baseline specification. As for the latter, we show that the managerial compensation or any other feature that is closely associated with the demand for managers did not influence the IPR reform through a series of exogeneity checks explicitly in the following section.

4.1 Exogeneity of The Patents (Amendment) Act, 2002

A crucial issue regarding our identification strategy is to establish that the timing of the 2002 IPR reform as exogenous, at least with respect to the internal reorganization activities of the Indian manufacturing firms. It may be that the previous IPR amendment bills or acts, say the one in 1999 led the firms to start demanding for managers anticipating the implementation of a stronger amendment act in the next few years and this influenced the differential effect on managerial compensation between high-tech and low-tech firms. Also, there may be other changes, which are

²⁴There were a couple of crucial changes in the realm of corporate governance reforms that took place around the implementation of The Patents (Amendment), Act, 2002: (i) exogenous changes in the Clause 49. The Clause 49 reform required firms to change the composition of their board of directors – specifically, at least 50% of the board had to consist of independent directors; and (ii) in 2002 the Securities and Exchange Board of India (SEBI) (Amendment) Act, 2002 replaced the earlier SEBI Act, 1992 to enlarge the Board of Directors of firms and transparent functioning of the Indian capital market. All these changes can induce a large number of firms to consistently report the compensation of the managers (especially, the top managers). However, we argue that is not the case. First, looking at **Figure 3** closely, it can be noticed that it is not only after 2002 that we observe a sharp rise in the share in managerial compensation; it was also during mid-1990s. If it had been only for the corporate governance reforms and nothing else, then we would have seen only a secular trend before 2002 and no spike. Chakraborty and Raveh (2018) show that the increase in the share of managerial compensation during the 1990s is due to the trade reforms undertaken by India. Second, even though the reform for the Clause 49 was adopted by SEBI in 2000, it was only in late 2002, SEBI constituted a committee to assess the adequacy of current corporate governance practices, and based on the recommendations of this committee, the Clause 49 came into operation on 1 January 2006.

coincident with The Patents (Amendment) Act, 2002 in terms of a high-tech firm’s behavior towards demand for managers. For example, there might be pressure by the big firms or multinationals to the Govt. of India to impose a stronger intellectual rights regime to create a certain kind of monopoly power over some products, which can reap them higher benefits. While, we cannot completely rule out these alternative explanations, we can examine their plausibility more carefully. To understand, whether such are the cases or not, we run some checks in **Table 3**.

We start by checking whether the 1999 Patent Act has a proactive effect on the share of managerial compensation. In other words, we examine if the observed effect of 2002 reform sustains, when we introduce the 1999 reform. Column (1) interacts the 1999 reform dummy, IPR_{99} , with our *HighTech* dummy. We define IPR_{99} as a time dummy, which takes a value 1 if the year is greater than or equal to 1999. Our variable of interest, $IPR_{02} \times HighTech$, is positive and significant with no effect of the $IPR_{99} \times HighTech$. In column (2), we replace our *HighTech* dummy in the interaction term $IPR_{99} \times HighTech$ with $HighTech_{98}$. $HighTech_{98}$ takes a value 1 if the average technological adoption expenditure of a firm for the years 1990 to 1998 is greater than the median technological expenditure of the industry to which the firm belongs. We do this to understand whether a firm, which was a high-tech before the 1999 Act, raised its demand for managers because of the 1999 reform and the 2002 reform was nothing but an additional push. We fail to find any evidence of such kind. In column (3), we additionally interact $HighTech_{98}$ with IPR_{02} in order to see if the high-tech firms were re-organizing their firm structure in anticipation to the 2002 reform. We find our coefficient of interest ($IPR_{02} \times HighTech$) to be positive and significant, with the additional interaction term not affecting our outcome of interest. In short, our results tell us that the 2002 IPR reform is not a mere extension of the 1999 reform, but an unanticipated change towards a stronger intellectual property rights regime.

Additionally, we run a placebo test with detailed estimates of the timing of changes in share of managerial compensation. In particular, we use an ex-ante ex-post approach to prove that The Patents (Amendment), Act 2002 is not endogenous. In other words, the estimation examines if there were any anticipatory effects of the reform. It could be possible that some of the high-tech firms were lobbying for the implementation of a stronger IPR regime to reap higher benefits and started reorganizing the firm structure accordingly. This could have increased the share of managerial compensation of the firms before the reform and post-2002 increase was just a mere continuation. We argue that this is not the case. We follow Branstetter et al. (2006) and adopt the

following methodology. The $IPR_{02}(t-4)$ dummy is equal to one for all years that predate the 2002 patent act by four or more years and is equal to zero in other years, and the $IPR_{02}(t+4)$ dummy is equal to one for all years at least four years after the IPR reform and zero during other years. The other reform dummies are equal to one in specific years and zero during other years. There is no dummy for the year immediately preceding the ban (i.e., year $t-1$); the coefficient on the reform dummy estimates relative to that year. The results indicate that the coefficients on the dummies for years prior to The Patents (Amendment) Act, 2002 fails to show any evidence of a significant movement in the demand for managers prior to the reform when estimated relative to the preceding year. For example, the coefficient on the $IPR_{02}(t-4)$ show that the managerial compensation of a high-tech firm is negative and insignificant prior to the reform relative to the concurrent effect of the reform, which is $IPR_{02} \times HighTech$. The coefficient of the interaction term of IPR_{02} and $HighTech$ continues to be positive and significant; whereas, the coefficient for the years after the reform are large, positive and significant. Thus, the timing of changes is consistent with a shift in activities that follows the enactment of the reform; the coefficients are positive, significant and increases over time.

We ran some further checks following Khandelwal and Topalova (2011) to test for potential lobbying effect and influence of the 1999 reform. In particular, we test whether the interaction of high-tech dummy and reform dummy is correlated with important pre-reform (pre-2002 but post-1999) industry characteristics, which may have influenced the 2002 reform. These characteristics include share of managerial compensation (a larger share of managers may influence the industry lobbyists to put pressure on the Govt. to adopt more stronger intellectual property rights), share of skilled workers (a highly skilled work force may also push for reforms in order to reap benefits from higher incentives to innovation) and average factory size (this captures the ability of producers to organize political pressure groups to lobby for stronger patent rights regime). All the pre-reform characteristics are measured at the year 2000-01. These results are presented in columns (5) – (7) in **Table 3**. The coefficients indicate no statistical correlation between the complementary effect of technology adoption and 2002 IPR dummy and any of the industry characteristics.

One possible explanation for these outcomes can be traced to Reddy and Chandrashekar (2017). They conduct a careful study of the dilemmas involved in the implementation of the reforms towards stronger protection of patent rights, showing that there was a lot of uncertainty involved during the debates and discussions in the parliament with regard to the implementation of

a TRIPs-compliant patent regime. Finally, we investigate whether the policymakers implemented the 2002 Act in response to firms' demand for managers. If this were the case, one should expect current share of managerial compensation to predict future implementation of the IPR reform due to the influence of the high-tech firms. We regress $IPR_{02} \times HighTech$ on share of managerial compensation in $(t - 2)$ period, controlling for firm and industry-year fixed effects. Column (8) presents the result from such an exercise. The correlation between future reform and current managerial compensation is indistinguishable from 0.

5 Results

In this section, we report our empirical findings on the effect of the IP reform of 2002 on the organization of Indian firms. We describe our results under three heads: managerial compensation, incentive provision and organizational design.

5.1 Managerial Compensation

We present our benchmark results from estimating equation (1) for the period 1990-2006 in **Table 4**. We provide different specifications by varying the fixed effects (firm, year, industry-year and so on) as well as the level of aggregation while always controlling for the age (including a quadratic term), ownership and size of a firm. These regressions estimate the effect of the IPR reform on the demand for managers in the intensive margin, i.e., as measured in terms of share of total compensation.

We find that in each of these specifications, the coefficient of the interaction term $IPR_{02} \times HighTech$ is positive, highly significant and roughly similar across specifications (1.6% – 1.7%). On the other hand, the coefficient of the variable IPR_{02} is positive and significant for the initial specifications, but becomes insignificant once we allow for industry fixed effects at sufficiently disaggregated levels. In other words, the increase in the demand for managers in the intensive margin is due to both within-firm effect as well the differences in the high-tech and low-tech firms, but the latter effect is stronger.

In column (6), we additionally interact the *HighTech* dummy with year dummies to control for the pre-trends that may influence our results using the following regression equation:

$$\left(\frac{Mcomp}{Tcomp}\right)_{it} = \alpha_i + \alpha_t + \alpha_{jt} + \beta_1(IPR_{02} \times HighTech_i) + \beta_2 IPR_{02} + \alpha_t \times HighTech_i + firmcontrols + \epsilon_{it} \quad (2)$$

The coefficient of the interaction term is still positive and significant. But, in this case it is smaller than the coefficient of IPR_{02} . This points out that when controlling for pre-trends, the within-firm wage inequality is higher than the between-firm, which is opposite to that of our finding in column (4). **Figure 5** plots coefficients from equation (2) for our main firm outcome variable, share of managerial compensation. The estimated coefficients illustrate that, the difference between the high-tech and low-tech firms in terms of share of managerial compensation is not significantly different from zero before the patent reform of 2002. However, share of managerial compensation rises differentially for high-tech firms after 2002.

In column (7), we use simple Average Treatment Effect (ATE), which measures the difference in mean (average) outcomes between the units assigned to the treatment (high-tech firms) and control (low-tech firms) group, respectively. Our estimates suggest that the 2002 IPR reform increases the relative demand for managers gap between high-tech and low-tech firms by 1.6-1.7% at the mean, which is the same as the estimate from our OLS regressions. Lastly, in columns (8) and (9), we divide the managerial compensation between middle and top managers to see the variation in effect across managerial layers. Share of compensation across firms increases for both the management levels, albeit higher for the top than the middle. However, on the other hand, there is no within-firm effect in case of top managers; the entire effect is concentrated for middle managers.²⁵

Managerial share of total compensation is a measure of demand for managerial skill in the intensive margin. Columns (1) and (2) of **Table 5** performs the same analysis for demand for managers in the extensive margin by treating the total number of managers²⁶ as the outcome variable. We see that while the IPR reform has had no within-firm effect on the extensive margin

²⁵We also use absolute level of total managerial compensation, disaggregated into top and middle level, as the dependent variable. We report the results in **Table 13** of **Appendix B**. Our coefficient of interest continues to be positive and significant.

²⁶PROWESS provides names of the managers at the top and middle management level. We count the names to calculate the number of managers in a firm across different years. We note that the names of the managers belonging to the middle management are not as consistently reported as top management. So, when we match the data (with the number of managers across both management levels and compensation), the number of observations drop significantly. However, that is not the case with only the top management. If we use only the top management data, then the number of observations rise significantly and our result continues to hold.

but the between-firm effect is positive and significant, i.e., the reform caused the high tech firms to employ 6.3% - 6.9% more managers than the low tech firms at the mean. While the extensive margin considers the effect of IPR on “quantity” of managers employed, columns (3) through (6) looks at the average “price” of managers. We now treat as dependent variable the average compensation of managers obtained by dividing the total compensation with the number of managers in a firm. Columns (3) and (4) tell us that both the within- and between-firm effect are positive and significant when we look at managers as a whole. Columns (5) and (6) looks at the average compensation for middle managers and top managers respectively. While we obtain the same pattern as the overall, there is an interesting difference across levels: the between-firm effect is stronger (both in significance and magnitude) for top managers and the within-firm effect is similarly stronger for middle managers.

In **Table 14** in the **Appendix B**, we perform a set of similar exercises for non-managerial employees.²⁷ We find that, in terms of non-managerial share of total compensation, the within-firm effect is positive while the between-firm effect is negative. Moreover, while there is no significant effect of IPR on average compensation, there is a positive effect on employment both through the within-firm and between-firm channels.

Combining all the results, it points out to the fact that the 2002 IPR reform did increase a manager’s internal worth to the organization and its average value in the market more for the high-tech firms than the low-tech. On the other hand, while the same reform led to an increase in non-managerial employment, their share of compensation went down since their average wages remained virtually unchanged across the economy. In a somewhat similar context, Vashisht (2017) finds that adoption of new technology has increased the demand for high-skilled workers at the cost of intermediary skills, leading to the polarization of manufacturing jobs in India. These results may suggest that technology has reduced the routine task content of manufacturing jobs in India.²⁸

5.2 Disaggregating Compensation into Wages and Incentives

Our analysis so far indicates that the 2002 IPR reform has a significant positive impact on the relative demand for managers in the high-tech firms more than that of low-tech firms. Now, we

²⁷We note that PROWESS provides very limited data (only for about 250 firms) on the total number of employees. We do not claim that using data for such a small number of firms can be generalized, but it gives an idea of what happened on the non-managerial side of the firms.

²⁸Garicano (2000) argues that managerial skill is important for non-routine tasks in the production processes.

examine how this IPR reform influenced the form of managerial compensation across firms.

There is considerable debate in the literature about the role of performance incentives in motivating innovation. Holmstrom (1989), Teece (1994) and Amabile (1996) indicate that short-term performance incentives may not be conducive to generating effort towards innovative activities. Lerner and Wulf (2007) and Kline et al. (2017) point out the value of long term incentives for innovation. We, however, find an increase in incentive share of pay especially for high tech firms.

We disaggregate the compensation into wages and incentives by different management layers and present the results in **Table 6**. We define as incentive pay, a part of compensation reported, as the following heads: (a) benefits or perquisites; (b) bonuses and commission; (c) contribution to provident fund; and (d) contribution to pension, whereas wages are considered to be the pre-determined component of the total compensation salary received by the employees. Columns (1) and (4) examine managers' share of total wage compensation, $Mwages/Twages$, and managers' share of total incentive pay, $Mincentives/Tincentives$, similar to our outcome of interest in Equation (1).

Notice first that the coefficient of the interaction term in column (1) is negative and weakly significant, and the same in column (4) is positive and highly significant. Therefore, differences between high-tech and low-tech firms in terms of demand for managers is only due to the difference in share of incentives. On the other hand, the within-firm effect is positive for managers' share of wages but insignificant for managers' share of incentives. This result is consistent with empirical findings elsewhere that a positive external shock (e.g., trade liberalization) brings about an increase in managerial compensation through an increase in incentive pay (Cunat and Guadalupe, 2009; Chakraborty and Raveh, 2018). Our result that incentive driven increase is concentrated in high-tech firms is also reminiscent of the conclusion in Acemoglu et al. (2006) that firms closer to the technological frontier provide sharper incentives to their managers.

Columns (2), (3), (5) and (6) provide the effect of IPR on wage and incentive compensation of top and middle management separately. As mentioned before, we consider managers with executive powers as part of the top management and those without executive powers (typically, divisional managers) as belonging to the middle management. We find that IPR positively impacted the incentive pay of the middle management (both within- and between-firms) but the effect of IPR on incentive share of the top management is only visible across firms. For wage share, the negative overall between-firm effect comes entirely from the top management while the within-firm effect is

positive for both layers.²⁹ Therefore, the increase in managerial compensation for high-tech firms relative to low-tech firms should be attributed mostly to the increase in the share of incentive pay for executives in the middle management. Our result, then, contradicts the suggestion in Olney and Keller (2017) that external shock can lead to increased pay inequality due to top management executives paying large bonuses to themselves.

5.3 Organizational Architecture

Teece (1994) points out that adoption of new technologies by a firm leads to implementation of new organizational forms. In a similar context, Little (1985, p.14) highlights that “Our work among innovative companies indicates that the management decision on how to organize for innovation is critical”. We have already noted that the impact of IPR on the relative demand for managers in high-tech firms was different from that on low-tech firms. We now look into how the effect of IPR on internal organization varies across these two categories of firms. We study the organizational change both in terms of horizontal and vertical expansion, and present the results in **Table 7**.

A horizontal expansion refers to the addition of new divisions with similar managerial and non-managerial layering. While PROWESS does not provide details of the number of divisions in a firm, we proxy horizontal expansion by the number of product varieties (following a suggestion in Guadalupe and Wulf, 2010). Columns (1) and (2) indicate that IPR reforms force a high-tech firm to introduce significantly more product varieties than a low-tech firm (and possibly open more divisions).

In the spirit of Garicano (2000) and the related literature (Caliendo et al., 2015; Cruz et al., 2018), we think of vertical expansion as addition of hierarchical layers between the CEO and the non-managerial workers. Our data allows us to identify three layers: top management (i.e., managers with executive powers like the CEO, CFO, etc.),³⁰ middle management (e.g., divisional managers) and the non-managerial employees. We introduce a variable that counts the number of vertical layers in a firm (i.e., taking values 1, 2 or 3). We assume that each firm must have one management layer, possibly the top management. We can identify whether there is a middle management based

²⁹We have also checked the results for wages and incentives for each group (all managers, top management and middle management) as a share of total compensation. The results do not change. **Table 15** reports our additional findings.

³⁰However, our data can also allow us to follow the classification of Caliendo et al. (2015), where they categorized only the CEOs as the top management layer and other managers with executive powers as the layer below the top management. But, we have decided to combine these two layers into 1.

on the compensation and designations of the managers provided. However, PROWESS does not provide names of non-managers. So, we consider a firm to have a non-managerial layer if the total compensation of non-managers is reported to be positive.³¹

Columns (3) and (4) considers the effect of the 2002 IPR reform on the vertical dimension of a firm. Our coefficient of interest points out that the 2002 IPR reform significantly increased the differences in hierarchical structure between high-tech and low-tech firms. Similar vertical expansion due to external shocks have been studied in other contexts in Caliendo and Rossi-Hansberg (2012), Caliendo et al. (2017) and Cruz et al. (2018).

These results demonstrate that the 2002 IPR reform induced both vertical and horizontal expansion for high-tech firms relative to their low-tech counterparts. Next, we check which dimension of expansion is the main driver behind the increased relative demand for managers. We interact both the number of vertical layers as well as product scope with our original interaction term $IPR_{02} \times HighTech$, in the regression for relative demand for managers.³² Our conditional correlates in column (5) and (6) point out that the increase in the demand for managers are due to the adding of new products by a firm rather than adding a vertical layer. In other words, the higher relative compensation for managers can be attributed to the fact that high tech firms respond to IPR by increasing product innovation which leads to new divisions being opened, leading to subsequent demand for managers. This result stands both in support and contrast to the literature looking at firm reorganization and knowledge optimization as a result to market forces.³³ Guadalupe and Wulf (2010) and Chen (2017) shows that import competition can lead a firm to expand horizontally, whereas Caliendo and Rossi-Hansberg (2012), Caliendo et al. (2015; 2017), Spanos (2017), Cruz et al. (2018) seems to focus more on vertical adjustment as a result to external shocks such as trade, productivity, etc.

5.4 Firm Characteristics

We now examine additional heterogeneity in **Table 8** using various firm characteristics to identify the set of firms, which drive the main result(s). We start by dividing the sample into exporters and

³¹We only consider the firms for which the non-managerial compensation is reported to be non-zero. Admittedly, our definition of layers is very coarse and what we capture is effectively the probability with which firms add a middle management due to the IPR shock.

³²Our regressions include all the respective double interaction terms.

³³Caroli and Van Reenen (2001) using data on French and British establishments show that technological adoption leads to decentralization of authority or increases a manager's span of control.

non-exporters in columns (1) and (2). The coefficients show that the differential response in the demand for managers is significant for both exporters and non-exporters, with the effect significantly higher for the latter group of firms. Interestingly, on the other hand, the within-firm effect is higher for exporters. We believe that this result is due to the fact that to begin with, exporting firms as a group are much more similar in terms of technological expenditure than non-exporting firms.

Next, we divide firms by ownership – domestic and foreign in columns (3) and (4). The interaction effect of $IPR_{02} \times HighTech$ is significant for both domestic and foreign firms, with the effect slightly higher for foreign firms. In terms of within-firm effect, we find a similar effect (in terms of magnitude) for domestic firms and no effect for foreign firms. Lastly, in columns (5) and (6) we follow Nouroz (2001) and use the input-output classifications to categorize firms by the end use of their products. The division is made into two groups – intermediate (intermediates, basic and capital) and final (consumer durables and non-durables) goods. The interaction effect is significant for both classes of firms. Overall, our findings show that an IPR shock has an economy-wide effect in comparison to trade or other marcoeconomic shocks, where the effect is limited to only a few sections of firms such as exporters (Caliendo and Rossi-Hansberg, 2012).

5.5 Sensitivity Analysis

We check for the robustness of our results by using several controls, alternative techniques, sample and time period in **Tables 9, 10, 11** and **12**.

5.5.1 Additional Controls

This section controls for all other possible channels that can simultaneously affect the managerial compensation of a firm. While some of these channels do have significant effects, our primary result remains true and significant in every case establishing the fact that IPR reforms indeed contribute to a higher relative demand for managers for high-tech firms.

Trade Shocks: We start by controlling for all possible trade channels that can concurrently affect managerial compensation and present the results in **Table 9**. Recent research by Caliendo and Rossi-Hansberg (2012) points out that trade significantly affects organizational structure of firms through increase in demand for managers (Cunat and Guadalupe, 2009; Chakraborty and Raveh, 2018). Chakraborty and Raveh (2018) uses the trade liberalization exercise adopted by

India during the 1990s to examine its effect on the demand for managers and show that drop in input and not output tariffs significantly explains the rise in the share of managerial compensation for Indian manufacturing firms. We use the same indicators and interact them with *HighTech* in columns (1), (2) and (3). Our results indicate that both input and output tariffs significantly increased the difference in the demand for managers across high-tech and low-tech firms. However, we do not find any statistically significant effect when we use them jointly.

Cunat and Guadalupe (2009) and Guadalupe and Wulf (2010) show that import competition and product market competition significantly affects managerial or executive compensation. We use Chinese competition as a proxy for import competition.³⁴ We use two different indicators for Chinese import competition in columns (4) and (5) to measure such effect. PROWESS does not give any information regarding the trade destinations of the firms. To overcome such a shortcoming, we match the firm-level data from PROWESS with the trade-destination based product level UN-COMTRADE dataset at NIC 2004 4-digit level. To establish causality between import competition and managerial compensation, we follow Chakraborty and Henry (2017) and use China’s entry to the WTO on December 11th, 2001 as a quasi-natural experiment, together with the differential competitive pressures faced by Indian firms due to this trade shock, as our identification strategy. We use the following index:

$$\begin{aligned}
 AvgM01_j^{China} &= Avg_{1992-2001} \left[\frac{imports_{jt}^{China}}{imports_{jt}^{Total}} \right] \\
 &= Avg \left[\frac{imports \text{ from China for the years } 1992-2001 \text{ for the industrial category } j}{imports \text{ from World for the years } 1992-2001 \text{ for the industrial category } j} \right]
 \end{aligned}$$

Thus, we define $AvgM01_j^{China}$ as a measure of Chinese competition that an industry faces because of the unilateral liberalization policies pursued by China; it is a 10-year average of the share of imports by industry j for the period 1992-2001. We interact this measure with WTO_t . WTO_t is a year dummy variable intended to capture the effect of China’s entry into the WTO. It takes a value of 1 for the years following the signing of the WTO agreement by China. Therefore, WTO_t equals 1 for the years 2002-2006. So, our variable of interest, $AvgM01_j^{China} \times WTO_t$, provides a measure of the amount of competition faced by Indian firms as a result of China becoming a member of the WTO. The interaction term $AvgM01_j^{China} \times WTO_t$ provides a clear and exogenous measure

³⁴India’s imports from China increased from around 1% in 1992 to 17% in 2006; the increase in the share is especially sharp between 2001 and 2006, from 5.5% to 17%.

of import competition from China and represents a difference-in-differences approach to measure the effect of Chinese import competition on the product variety of Indian manufacturing firms. In order to measure the differential effect of the Chinese import competition on the managerial compensation, we interact $AvgM01_j^{China} \times WTO_t$ with our *HighTech* dummy. We fail to find any statistically significant effect of domestic competition from Chinese imports.³⁵

Next, in column (5), we use an alternate measure of Chinese import competition. We use lagged value of the share of imports from China at NIC 2004 4-digit level weighted by sales share of those industries. We continue to find no effect of Chinese import competition.

Caliendo et al. (2017) argue that participation in export market significantly increases executive compensation. In column (6), we use the share of India’s exports in total imports of the US to see whether export market competition has positively affected the demand for managers. We find negative effect of the interaction term with weak significance. Higher participation in the export market closes the gap between high-tech and low-tech firms in terms of demand for managers.

Other Possible Channels: We follow Chakraborty and Raveh (2018) and test for other industry- and firm-level channels in **Table 10**. We start by testing the potential correlation between relative demand for managers and skilled labour. We measure the latter using the 3-digit industry level ratio of non-production workers to all employees in an industry, obtained from Ghosh (2014) (1990-2000), and the ASI (2001-2006). The main result continues to hold, suggesting that it is not driven only by increases in the demand for skill. However, our outcome variable of interest and skill intensity appears to be significantly correlated. This suggests that capital-skill complementarity might also be a channel through which demand for managers increased because of higher technology adoption due to the IPR reform.

Column (2) uses management technology and its interaction with *HighTech* dummy as an additional control. We use data on management technology from World Management Survey. It is given for a single year, which is 2004 across all the NIC 2004 2-digit industries. Our estimates point out that management technology of an industry is positively and significantly correlated with the demand for managers, but this is a complementary additional effect with our main variable of

³⁵We also check our results by looking at Chinese competition in one of India’s important export market, the U.S. We use the Chinese share of imports by the U.S. to check whether competition from China in India’s one of the most important trade destinations lead to such changes in the share of managerial compensation of firms. We do not find any such evidence.

interest still positive and significant. Establishment of new factories may create a demand for new managers, as local knowledge is important (Bloom et al., 2010). Therefore, we use an additional related measure: the number of factories and plants at the industry-level, derived from ASI. The inclusion of this additional control does little to change our benchmark finding.

Bloom et al. (2013) points out that better managed firms in India have higher productivity. To address this, we control for productivity using Levinshon and Petrin (2003) methodology in column (4). As the results demonstrate, more productive firms demand more managers, but our coefficient of primary interest is stable in sign, magnitude and significance.

One can argue that the sudden expansion in Information Technology enabled services (ITES) in early 2000s can explain some of the increased relative demand for managers in the high-tech firms that we ascribe to IP reforms. In order to control for this, we use expenditure incurred by firms towards in-house information technology and consultancy fees for technological upgradation in column (5). We find consultancy fees for technology upgradation to be significantly correlated with the share of managerial compensation. However, the sign and significance of our main channel does not go away.

As highlighted by Bloom et al. (2013), family firms may use their control over the Board of Directors to appoint their family members in several of the managerial positions within the firm and this could increase the managerial compensation. We construct an indicator for family ownership by considering the proportion of shares held by Hindu undivided families from 2007 (which is the first year for which PROWESS reports such data) and assuming that such proportion remained constant over the period 1990-2006. In column (6), we interact the family-ownership indicator with $IPR_{02} \times HighTech$ and see whether family firms influence any increase in the share of managerial compensation or not. We do not get any such evidence.

Olney and Keller (2017) suggest that the increase in managerial compensation during a trade shock may be explained by the fact that the top management gets to decide its own pay. In order to check if our results can be explained by the lack of good corporate governance, we use the number of independent directors in the Board of a firm as an indicator of quality of governance. Since most firms started reporting the composition of their boards from 2003-2004 onwards, matching the number of independent directors with our main dataset running from 1990 till 2006 drops around 90 percent of the observations. In column (7) we report the results from this control. None of the regressors are significant, including our main variable of interest; but the sign of the coefficient does

not change.

Lastly, following Bloom and Van Reenen (2010), we control for cross-regional variation in labour market rigidity in India in order to check if the sharper response of high-tech firms to IP reforms appears due to a possible concentration of high-tech firms with more flexible labour market regulations. Accordingly, we use the postcode for each firm to locate its state/region and then interact the state-year fixed effects to control for the variation in labour regulations across different states in India in column (8). Our baseline result does not change.³⁶

5.5.2 Trend-Break Analysis

Following Burgess and Pande (2005), we estimate a trend break model to control for the differential time trends that may affect our outcome variable(s) using the following specification

$$\begin{aligned} \left(\frac{Mcomp}{Tcomp}\right)_{it} = & \alpha_i + \alpha_t + \alpha_{jt} + \beta_1[HighTech_i \times (t - 2001)] + \beta_2[HighTech_i \times (2002 - 2006)] \\ & + \beta_3[IPR_{02} \times (t - 2001)] + \beta_4[IPR_{02} \times (2002 - 2006)] + firmcontrols + \epsilon_{it} \end{aligned} \quad (3)$$

Here, $(t - 2001)$ is a linear time trend and captures the differential pre-trend and post-trends of the 2002 patent reform, whereas $(2002 - 2006)$ is fixed time trend of the 2002 patent Act. These terms enter the regression interacted with our *HighTech* and *IPR₀₂* dummy. The time trends have a switch in 2002 because of the implementation of the Patent Amendment Act (2002). If the patent reform of 2002 has significantly influenced the demand for managers, we expect the interaction terms of the $[2002 - 2006]$ trend with *HighTech* and *IPR₀₂* dummy to be significantly different from the pre-trend interactions. Results are reported in **Table 11**. We test for this using share of managerial compensation (columns (1) – (2)), total number of managers (column (3)), and average managerial compensation (column (4)) as the dependent variables, respectively.

Our coefficients show that the post-trends are significantly different from pre-trends. For exam-

³⁶Besley and Burgess (2004) divides all the major Indian states based on the amendments done by each state on the Industrial Disputes Act (IDA) into three categories: pro-worker, neutral or pro-employer. We interact the index from Besley and Burgess with our variable of interest, $IPR_{02} \times HighTech$, and ran our regression. The estimate does not change. A recent OECD study on state-level labour reforms in India uses a survey to identify the areas in which states have made specific changes to the implementation and administration of labour laws. The regulations covered by the state specific survey goes well beyond the IDA and include the Factories Act, the Trade Union Act, and Contract Labour Act among others. We also use the OECD (2007) indicator to replace the Besley and Burgess (2004); our baseline result still does not alter.

ple, the effect of 2002 IPR reform on the share of managerial compensation for the high-tech firms, $HighTech \times (2002 - 2006)$, is five times higher than pre-trend. In case of number of managers or the extensive margin, we do not see any effect of pre-trends. Lastly, in case of average managerial compensation, the result continues to be the same – the post-trends are significantly different from pre-trends.

5.5.3 Other Robustness Checks

In **Table 12**, we start by changing the time period under consideration from 1990-2006 to 1990-2005. The reason for doing so is that 2005 is a crucial year when India finally complied with the TRIPs agreement and this could influence the outcome of interest. Reducing the time period does not affect our benchmark finding – the complementarity effect of IPR reform of 2002 and technology adoption continues to significantly explain the difference in the demand for managers between high-tech and low-tech firms. Column (2) aggregates our dependent variable ($Mcomp/Tcomp$) and $HighTech$ to the industry-level (formally, $HighTech_i$ is replaced by $HighTech_j$, where j denotes an industry). An industry is categorized as $HighTech$ if its average technological expenditure for the period 1990-2001 is greater than the median technological or innovation expenditure of the whole of manufacturing sector. The motivation to do this is to check whether the differential effect holds between these different types of industries as well. The results suggest that the 2002 IPR reform also led to larger increase in demand for managers in high-tech industries. In other words, our benchmark result is robust to this kind of aggregation.

Column (3) runs a placebo test. We drop all firms except for those in the pharmaceutical sector from the sample. The reason to do this are twofold: (i) the pharmaceutical firms are known to be the early adopters of technology as compared to other manufacturing sectors; and (ii) unlike other sectors, product patents were already allowed for the pharmaceutical sector prior to 2002. Given these primitives, we should not expect any effect of the reform of 2002 on the pharmaceutical firms. The estimate shows our hypothesis to be true.

Big firms pay disproportionately larger compensation to their managers and this can also influence the overall results (Autor et al., 2017). To correct for such bias, we drop firms, which are greater than 90th percentile of the total assets of the industry to which the firm belongs in column (4). The baseline coefficient does not change.

Since our dependent variable is a ratio, estimating zero-valued variables with OLS may produce

biased estimates. So, we use fractional logit and Poisson Pseudo-Maximum Likelihood (PPML) (Silva and Tenreyro, 2006) in columns (5) and (6) to control for such. Both the methods estimate the coefficients in terms of percentage changes and the dependent variable does not need to follow a Poisson distribution or be integer-valued (it can be continuous).³⁷ As the point estimates demonstrate, the 2002 IPR reform continues to induce significant increase in the relative share of managerial compensation.

6 Discussion of Results

We find that the change in intellectual property rights regime in India, as encapsulated in the Patent (Amendment) Act, 2002, had the following effects. The IP reform led to an increase in managers' compensation as a share of total labor compensation as well as the employment share of managers. This increase in the relative value of managers is significantly more for firms that were technologically advanced before the reform. Additionally, there is also a within-firm shift in the demand for managers, but the between-firm effect is more consistently significant across specifications. This increase in relative demand is driven by the demand both for top and middle managers. Disaggregating the total managerial compensation into wages and incentives, we see that it is the share of incentives rather than wages that explains the difference between high-tech and low-tech firms. The rise in incentives is stronger for the middle management than for the top management. Looking at organizational design, we find that IPR induces firms to expand in terms of hierarchical layers as well as horizontal span of control, more so for high-tech firms. Importantly, it is the horizontal rather than vertical expansion that explains the increase in managerial compensation in high-tech firms. Lastly, these effects hold across exporters and non-exporters, domestic and foreign firms as well as firms producing final or intermediate goods. We now try to reconcile these findings with the related literature and seek to find the channels through which an IPR reform may raise the demand for managers.

Acemoglu and coauthors, in a series of papers (Acemoglu et al., 2006; Acemoglu et al., 2007) hold that managerial skill is more valuable to firms closer to the technological frontier, and in particular for firms engaged more in innovation than imitation. The IPR reform in India increased the relative value of product innovation over process imitation by introducing monopoly rights over

³⁷We estimate the standard errors using Eicker-White robust covariance matrix estimator.

new products. As a result, there was an economywide increase in demand for managers. In addition, since technology intensity is complementary to managerial skills at the intensive margin, we find that the increase in relative demand for managers is stronger for more technologically advanced firms.

While we measure technological intensity by R&D expenditure and technology transfers, there is a clutch of other complementary factors associated with technological advancement (e.g., ICT, management technology, expenditure in physical capital etc.). There is a large literature examining the correlation between these factors with innovation expenditure, organization design and demand for skilled labour (Bresnahan et al., 2002; Brynjolfsson and Hytt, 1998; Burstein et al., 2016; Caroli and Van Reenen, 2001; Guadalupe et al., 2014). We find that each of these has an independent effect on the increase in relative demand for managers, which is thus consistent with the large literature on capital-skill complementarity. However, even after controlling for these factors, we find that technology intensity of inputs has a statistically significant effect on share of managerial compensation for high-tech firms.

Our results are consistent with the idea of a firm as a problem solving entity enunciated in Garicano (2000). The production process essentially involves workers solving a flow of problems. Unsolved problems travel up the organizational layers, and a manager's role is to attend to the exceptional problems occurring within his/her span of control. The organizational hierarchy is designed to optimize managers' time and maximize problem solving efficiency.

The IPR reform increases the value of new products, and as the firm undertakes more new product development the complexity of the problems faced by the firm increases significantly. Since the production workers (non-managers) are faced with more challenging or exceptional problems, the role of the manager becomes more valuable to the firm. This explains the increase in the demand for managers relative to production workers consequent to the IPR reform. In addition, we should also expect the IPR shock to increase the number of managerial layers in order to better handle the increased volume of exceptional problems. In related work, Caliendo and Rossi-Hansberg (2012) demonstrate evidence of vertical expansion due to a trade shock and explain it using the Garicano framework. Spanos (2017) also uses this framework to explain increase in hierarchical layers due to demand expansion.

Our results, especially the between-firm increase in demand for managers is consistent with the idea of IPR reforms inducing patent-races (Branstetter et al., 2006). While product patents

increased the gains from product innovation, the firms that were already technologically advanced had a deeper stock of technical knowledge, skills and resources and therefore were at an advantage in such races. Therefore, the expected gains from new product development increased more for firms already ahead in the race.

Our data shows a sharp rise in performance pay especially for high-tech firms while the larger literature provides at best mixed support for short term incentives as a way of motivating innovation (Tece, 1994; Amabile, 1996; Lerner and Wulf, 2007; Kline et al., 2017). On the other hand, similar increase in incentives have been reported due to trade shocks or increased market competition (Cunat and Guadalupe, 2009; Keller and Olney, 2017). We hypothesize that the new IPR regime suddenly created a climate of competition among firms in the race to capture monopoly rights. In this environment, the increase in performance pay was possibly a measure adopted by firms in order to motivate managers to not only engage in innovation but to innovate fast enough to be able to win the patent race.

Our results about organizational structure validate this idea of managers being incentivized for patent races. There was a sharp increase in the number of new products introduced by high-tech firms, and we believe that there was an associated increase in the number of divisions. The shift in compensation structure towards incentives was sharper for middle managers who were typically the divisional heads. In fact, the benchmark result of increase in relative demand for managers in high-tech firms is strongly correlated with this horizontal expansion rather than the vertical expansion. Notice that it is these middle level managers, i.e., heads of product divisions and managers of functions like R&D, production, marketing, strategy etc. that drive the entire process of conceptualizing and bringing a new product to the market. We believe that the main effect of IPR on firm structure was a sharp increase in the employment and compensation of middle managers in high-tech firms, and sharper provision of incentive to these managers in order to reduce the time to market for new products.

It is important to recall here that such incentives indeed translate to higher patent output. As **Figure 6** shows, while the pattern of average patent claims were similar in both high-tech and low-tech firms before 2002, there is a sharp increase in such claims only for high-tech firms after 2002. Our findings inform us on the debate on whether management practices can be improved through incentives or information (Bloom et al., 2017). In this debate, one side thinks of management practices as the optimal design for the particular environment while the other side considers

quality of management as any other technological input which can be increased through appropriate measures. While we do not observe changes in management practices, we find that sharper incentives indeed improve R&D output. In this sense, our results provide support for the idea of managerial input as any other factor of production.

We close this section with a comment comparing the IPR shock with a trade shock. Some of our results like increased demand for managers, higher between-firm wage inequality, sharper incentives, etc. have also been observed elsewhere due to increased competitiveness because of trade shocks. However, while a trade shock typically affects those industries that are engaged in export or import, we find that a change in property rights over innovation affects virtually all sectors of the economy. It is this pervasiveness of impact that underlines the importance of intellectual property as a lever of policy and driver of welfare.

7 Conclusion

We investigate the effect of an IPR reform on firm structure and whether this effect will be different for high-tech vis-à-vis low-tech firms. We argue that stronger patent rights due to an IPR reform will induce a high-tech firm to innovate more, creating higher demand for managers. This is driven by the complementarity between managerial skill, technology adoption and innovation. Our benchmark estimations indicate that the 2002 IPR reform led to an increase in the share of managerial compensation of an average high-tech firm as compared to low-tech firm by 1.6-1.7%. This effect is robust to various controls, specifications, estimation techniques and time periods. Our results provide suggestive evidence for a quality upgrading mechanism through capital-skill complementarity.

Our results are also indicative of the kind of changes a developing economy like India goes through with increasing formalization and integration with the global economy. Associated with the upgradation of quality in the technologically advanced firms, we find evidence of increasing wage inequality in two dimensions: between managers and non-managers as well as between high-tech and low-tech firms. Such wage polarization appears to be an important economic trade-off associated with globalization of developing economies.

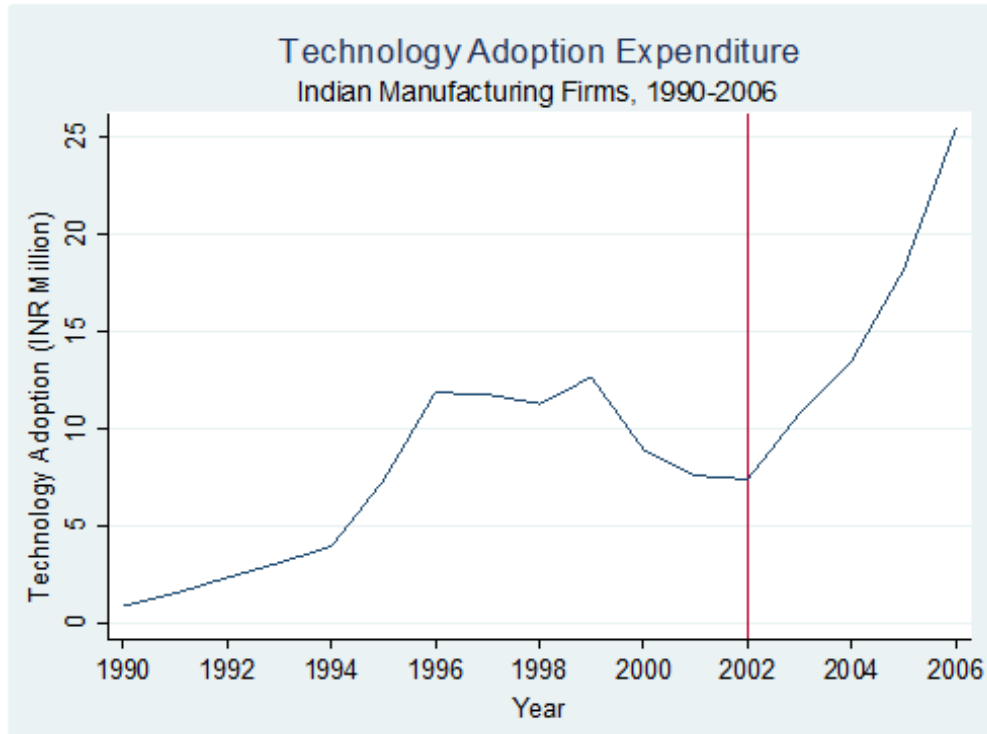

Figure 1: Technology Adoption Expenditure: Indian Manufacturing Firms, 1990-2006
 Notes: Figure presents the average technology adoption (sum of R&D expenditure and Technology Transfer) for manufacturing firms in India, 1990-2006

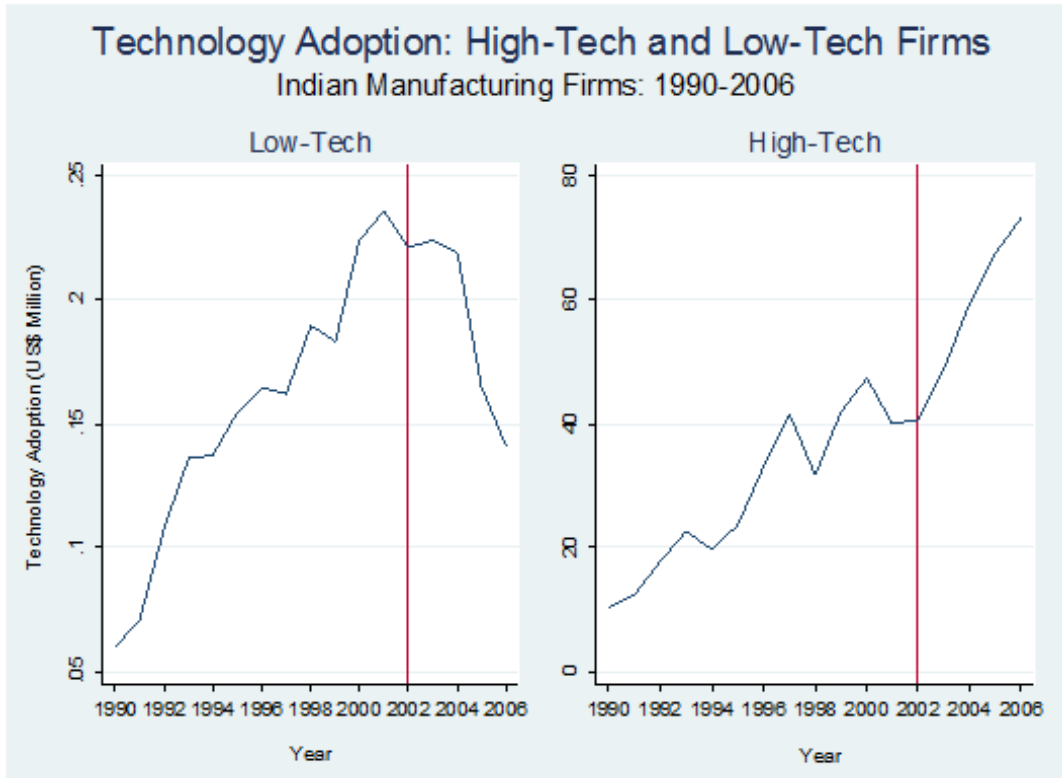

Figure 2: Technology Adoption: High-Tech and Low-Tech Firms, 1990-2006
 Notes: Figure presents the average technology adoption (sum of R&D expenditure and Technology Transfer) for manufacturing firms in India, 1990-2006

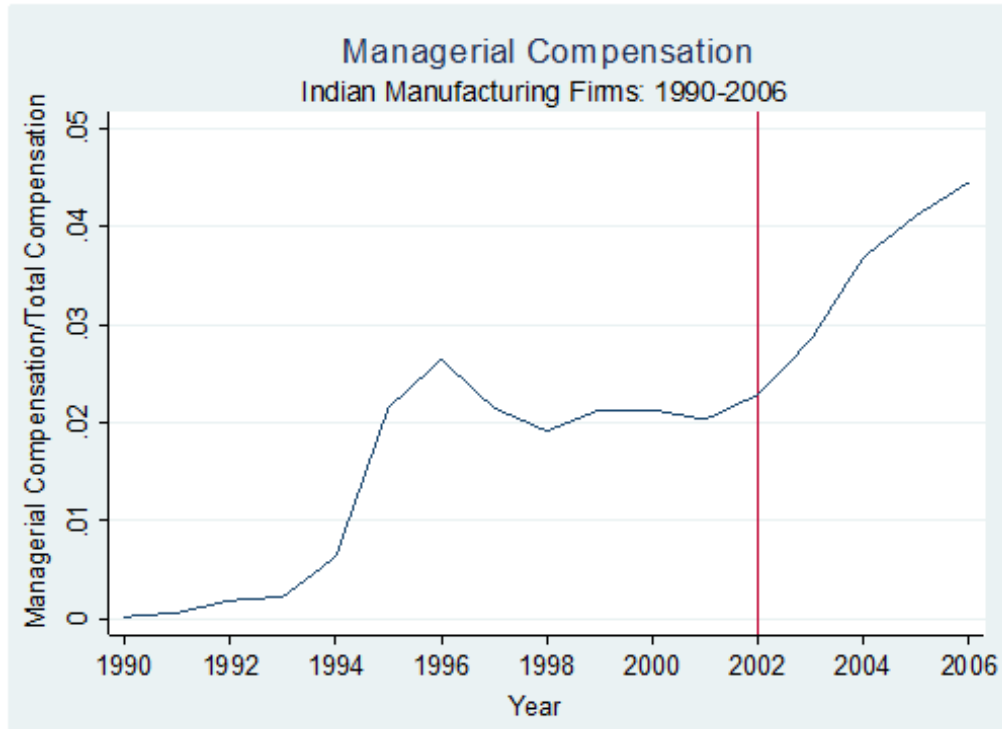

Figure 3: Managerial Compensation: Indian Manufacturing Firms, 1990-2006
 Notes: Figure presents the average share of managerial expenditure in total labour compensation for manufacturing firms in India, 1990-2006

Figure 4: Managerial Compensation: High-Tech and Low-Tech Firms, 1990-2006
 Notes: Figure presents the average share of managerial expenditure in total labour compensation for manufacturing firms in India, 1990-2006

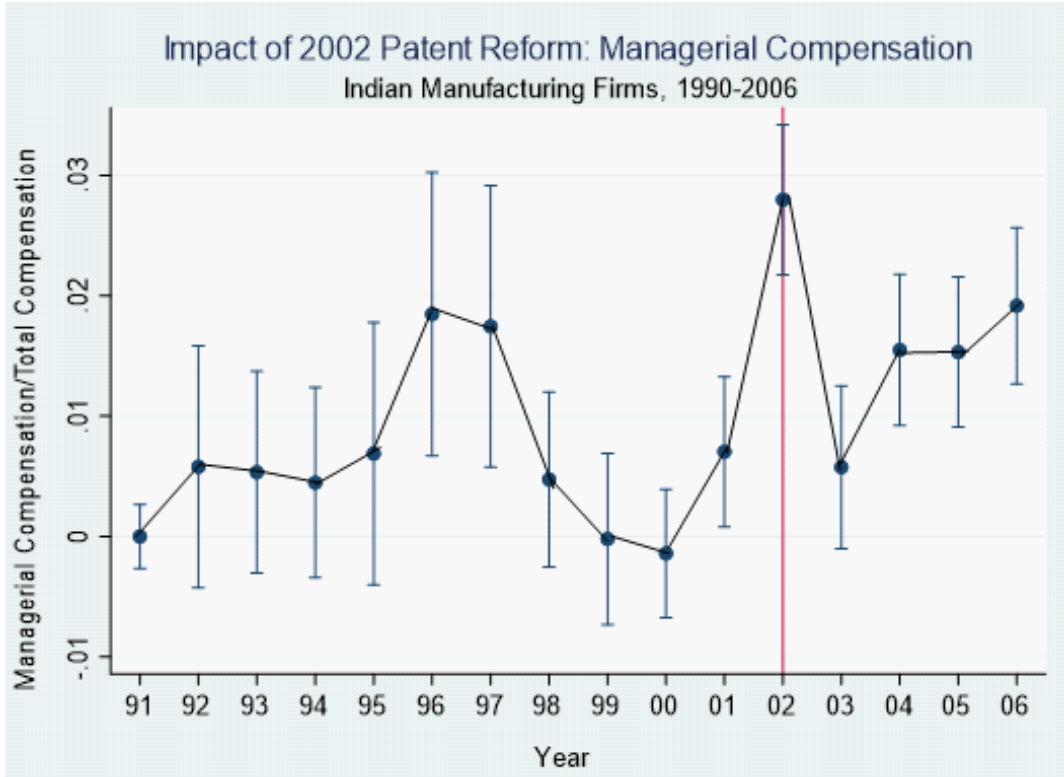

Figure 5: Impact of 2002 IPR reform: Managerial Compensation, 1990-2006
 Notes: Figure presents the response of the difference in the share of managerial compensation in total labour compensation for high-tech and low-tech firms in our sample for the period 1990-2006. 95% confidence intervals are shown.

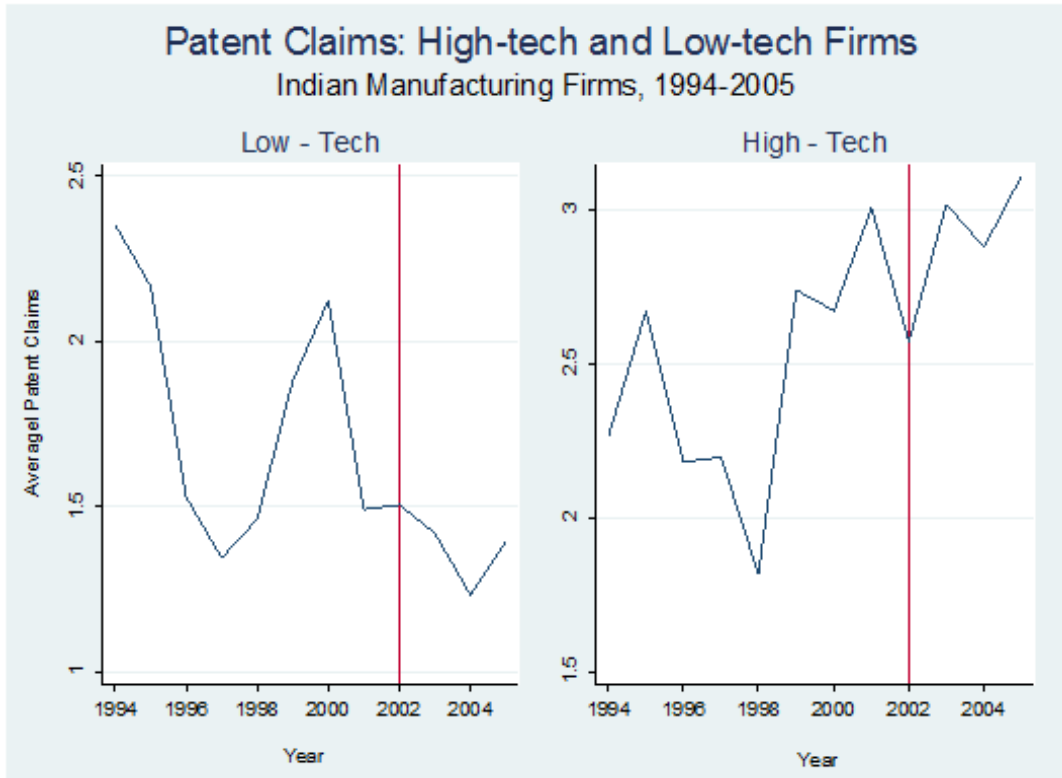

Figure 6: Patent Claims: High-Tech and Low-Tech Firms, 1990-2006

Notes: Figure presents the average patent claims filed with the Indian Patent Office for manufacturing firms in India, 1990-2006

Table 1: Comparison of High-tech and Low-tech firms

	Pre-ReformPeriod (1990-2001)		Post-ReformPeriod (2002-2006)	
	Low-tech	High-tech	Low-tech	High-tech
Technology Adoption/GVA	0.0031	0.0456	0.0019	0.7673
Managerial Comp/Total Comp	0.0122	0.0187	0.0219	0.0537
Capital/GVA	2.8870	3.7466	3.9477	3.9560
Imports/GVA	0.2853	0.3950	0.3042	1.3872
Exports/GVA	0.3132	0.2787	0.3930	0.5119
Sales/GVA	3.8528	2.7450	3.9927	4.5127

Notes: Annual data at the firm level, covering the period of 1990-2006. Numbers represent average values over the period mentioned.

‘Technology Adoption’ is defined as the sum of Research and Development Expenditure and Royalty Payments for Technical Knowhow (Technology Transfer). ‘Managerial Compensation/Total Compensation’ is the share of managerial compensation in total labour compensation. ‘Capital’ is the amount of capital employed by each firm. ‘Imports’ is total imports of a firm. Total imports is the sum of import of raw materials, capital goods, finished goods and store and spares. ‘Exports’ is total exports of a firm. ‘Sales’ is total sales (exports plus domestic sales). ‘GVA’ is the gross value-added of a firm. It is defined as total sales minus total expenditure on raw materials.

Table 2: Descriptive Statistics

	Mean	Median	Std. Dev.	Min	Max
Panel A: Organizational Variables - Dependent Variables					
Managerial Comp/Total Comp	0.02	0.003	0.08	0	1
Managerial Compensation	1.31	0.2	169.65	0	66315.1
Number of Managers	1.82	2	0.85	1	9
Non-Managerial Compensation	95.53	14.4	631.83	0	47619.5
Managerial Wages	0.63	0.04	147.11	0	57590.5
Non-Managerial Wages	93.73	13.6	624.18	0	39720.6

Consultancy Fees	8.13	0	217.53	0	46822.8

Notes: Annual data at the firm level, covering the period of 1990-2006. Monetary values are in real INR

Millions. 'Managerial Comp/Total Comp' is the share of managerial compensation in total labour compensation. 'Managerial Compensation' is the total managerial compensation. 'Number of Managers' is the total number of managers (middle plus top) in a firm. 'Non-Managerial Compensation' is the total non-managerial compensation. 'Managerial Wages', 'Non-Managerial Wages', 'Managerial Bonuses' and 'Non-Managerial Bonuses' is the total managerial wages, total non-managerial wages, managerial bonuses and non-managerial bonuses. 'Layers' is the number of vertical or hierarchial layers. 'Product Scope' is the number of products manufactured by a firm in a single year. 'Capital Employed' is the amount of capital employed by a firm. 'Technology Adoption/GVA' is defined as the share of the sum of Research and Development Expenditure and Royalty Payments for Technical Knowhow (Technology Transfer) in gross value-added of a firm. 'Assets' is the total assets of a firm. 'Tariffs (input and output)' are at the 3-digit NIC 2004. ' $(ChM/TotalM)_{India}$ ' is the share of Chinese imports in total imports of India. ' $(InM/TotalM)_{US}$ ' is the share of Indian imports in total imports of the US. 'Skill Intensity' is the ratio of non-production workers to total employees at the 3-digit NIC 2004. 'Management Technology' is a measure of management quality score obtained from Bloom and Van Reenen (2010) at 2-digit NIC 2004. 'Factories' is the number of factories at 3-digit NIC 2004. 'Productivity' is a firm level measure, estimated following the Levinsohn and Petrin (2003) methodology. 'IT Fees' is the amount of within-firm expenditure towards information technology services. 'Consultancy Fees' is the amount of expenditure incurred by a firm towards information technology services, but from external sources.

Table 3: Endogeneity of The Patents (Amendment), Act, 2002

	Managerial Compensation/ Total Compensation				Pre-Reform Characteristics			$IPR_{02} \times HighTech$
	1999 Reform			Ex-ante Ex-post	ManComp/ TComp	Skilled Workers	Factory Size

Firm FE	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Industry FE(2-digit)*Year FE	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes

Notes: Columns (1) – (4) use share of managerial compensation in total compensation as the dependent variable. Columns (5), (6) and (7) uses the share of managerial compensation, share of skilled workers and average factor size at period $(t-2)$ and column (8) uses ' $IPR_{02} \times HighTech$ ' as the dependent variable. IPR_{02} is a dummy variable, which takes a value 1 if year is greater than equal to 2002. ' $HighTech$ ' is a dummy variable which takes a value 1 if a firm's expenditure on account of R&D Expenditure and Technology Transfer before the year 2001, is greater than the median of the industry, to which the firm belongs. ' IPR_{99} ' is a dummy variable, which takes a value 1 if year is greater than equal to 1999. ' $HighTech_{98}$ ' is a dummy variable which takes a value 1 if a firm's expenditure on account of R&D Expenditure and Technology Transfer before the year 1998, is greater than the median of the industry, to which the firm belongs. '(Mcomp/Tcomp)_{t-2}' is the share of managerial compensation at $(t-2)$ period. ' $IPR_{02}(t-4)$ ' is a dummy which is equal to 1 for all years that predate the reform by 4 or more years and is equal to 0 in all other years. ' $IPR_{02}(t+4)$ ' dummy is equal to 1 for all years at least four years after reform and 0 during other years. The other reform dummies are equal to 1 in specific years relative to reform and 0 during other years. There is no dummy for the year immediately prior to the reform (i.e., year $t-1$); the coefficients on the reform dummies provide estimates relative to that year. 'Capital Employed' is the total amount of capital used by a firm at $t-1$ period. Firm controls include age, age squared of a firm and assets of a firm. 'Assets' is used as the size indicator at $t-1$ period. Both 'Capital Employed' and 'Assets' are expressed in their natural logarithmic form. Numbers in the parenthesis are robust clustered standard errors at the firm level. All the regressions include the individual terms of the double interaction terms. Intercepts are not reported. ^{a, b, c} denotes 10%, 5% and 1% level of significance.

Notes: Columns (1) - (3) and (4) - (6) use ratio of managerial wages to total wages, and ratio of managerial incentives to total incentives of a firm as the dependent variable, respectively. IPR_{02} is a dummy variable, which takes a value 1 if year is greater than equal to 2002. $HighTech$ is a dummy variable which takes a value 1 if a firm's expenditure on account of R&D Expenditure and Technology Transfer before the year 2001, is greater than the median of the industry, to which the firm belongs. 'Capital Employed' is the total amount of capital used by a firm at $t - 1$ period. Firm controls include age, age squared of a firm and assets of a firm. 'Assets' is used as the size indicator at $t - 1$ period. Both 'Capital Employed' and 'Assets' are expressed in their natural logarithmic form. Numbers in the parenthesis are robust clustered standard errors at the firm level. Intercepts are not reported. ^a, ^b, ^c denotes 10%, 5% and 1% level of significance, respectively.

Table 7: Intellectual Property Regimes and Firm Structure: Organizational Design

	Organizational Structure

Industry FE (5-digit)*Year Trend	Yes	Yes	Yes	Yes	Yes	Yes

Notes: Columns (1) – (5) use share of managerial compensation in total compensation and average managerial compensation as the dependent variable. ‘ $InpTariff_{t-1}$ ’ and ‘ $OutTariff_{t-1}$ ’ are input and output tariffs at 2004 NIC (National Industrial Classification) 4-digit level, respectively. ‘ $AvgM01^{China}$ ’ is the average imports from China at NIC 2004 4-digit level for the years on or before 2001 (1992-2001). ‘ WTO_t ’ is a year dummy, which takes a value 1 if the year is greater than or equal to 2002. ‘ MC_{jt}^{China} ’ is an alternative measure of Chinese import competition. It is an interaction of lagged value of Chinese share of imports in total imports of India weighted by sales share of each firm. ‘ XC_{jt}^{US} ’ is a measure of export market competition. It is defined as the lagged value of Indian share of imports in total imports of US. ‘ IPR_{02} ’ is a dummy variable, which takes a value 1 if year is greater than equal to 2002. ‘ $HighTech$ ’ is a dummy variable which takes a value 1 if a firm’s expenditure on account of R&D Expenditure and Technology Transfer before the year 2001, is greater than the median of the industry, to which the firm belongs. ‘Capital Employed’ is the total amount of capital used by a firm at $t - 1$ period. Firm controls include age, age squared of a firm and assets of a firm. ‘Assets’ is used as the size indicator at $t - 1$ period. Both ‘Capital Employed’ and ‘Assets’ are expressed in their natural logarithmic form. Numbers in the parenthesis are robust clustered standard errors at the firm level. Intercepts are not reported. *, **, ***, **** denotes 10%, 5% and 1% level of significance, respectively.

State FE*Year FE	No	No	No	No	No	No	No	Yes

Notes: Columns (1) – (8) use share of managerial compensation in total compensation and average managerial compensation as the dependent variable. ‘*SkIntens*’ is a proxy for skill intensity at the industry-level. It is defined as the share of non-production workers to total employees at the NIC 3-digit level. ‘*ManTech*’ is an index of Management Quality at 2004 NIC 2-digit level and has been sourced from Bloom and Van Reenen (2010). ‘*Factories*’ is the number of factories at 3-digit level NIC 2004. ‘*TFP*’ is total factor productivity at firm level estimated using Levinshon and Petrin (2003). ‘*ITFees*’ is the expenditure by a firm towards its information technology enabled services. ‘*ConsFees*’ is the expenditure by a firm towards its consultancy for technological upgradation or transfer. ‘*Familyfirm*’ is an indicator for family firm constructed based on the percentage of shares held by the Hindu undivided-family as promoters in 2007. ‘*IndDir*’ is the number of independent directors within the Board of Directors of a firm. It is an indicator for poor governance settings. ‘*IPR02*’ is a dummy variable, which takes a value 1 if year is greater than equal to 2002. ‘*HighTech*’ is a dummy variable which takes a value 1 if a firm’s expenditure on account of R&D Expenditure and Technology Transfer before the year 2001, is greater than the median of the industry, to which the firm belongs. Firm controls include age, age squared of a firm and assets of a firm. ‘Assets’ is used as the size indicator at $t - 1$ period. Both ‘Capital Employed’ and ‘Assets’ are expressed in their natural logarithmic form. Numbers in the parenthesis are robust clustered standard errors at the firm level. Intercepts are not reported. ^c, ^b, ^a denotes 10%, 5% and 1% level of significance, respectively.

Notes: Columns (1) – (6) use share of managerial compensation in total compensation as the dependent variable. ‘ IPR_{02} ’ is a dummy variable, which takes a value 1 if year is greater than equal to 2002. ‘ $HighTech$ ’ is a dummy variable which takes a value 1 if a firm’s expenditure on account of R&D Expenditure and Technology Transfer before the year 2001, is greater than the median of the industry, to which the firm belongs. ‘Capital Employed’ is the total amount of capital used by a firm at $t - 1$ period. Firm controls include age, age squared of a firm and assets of a firm. ‘Assets’ is used as the size indicator at $t - 1$ period. Both ‘Capital Employed’ and ‘Assets’ are expressed in their natural logarithmic form. Numbers in the parenthesis are robust clustered standard errors at the firm level. Intercepts are not reported. ^c, ^b, ^a denotes 10%, 5% and 1% level of significance, respectively.

Appendix

A Data

We use an annual-based panel of Indian firms that covers up to 8,000+ firms, across 108 industries within the manufacturing sector, over the period of 1990-2006 (with the exception of specific cases, where specified so). Unless otherwise specified, variables are based on data from the PROWESS database of the Centre for Monitoring Indian Economy (CMIE). All monetary-based variables measured in millions of Rupees, deflated to 2005 using the industry-specific Wholesale Price Index (derived from Allcott et al., 2016). All industry level cases are based on the 2004 National Industrial Classification (NIC).

Variable definitions

1. **Managerial compensation/Total compensation:** Share of managerial compensation in total labour compensation; compensation defined as the sum of all salaries, and additional bonuses.
2. **Total Managers:** Total number of managers in a firm. This is a sum of total number of managers at the top and middle management level.
3. **Average Managerial Compensation:** Total managerial compensation divided by total number of managers.
4. **Managerial wage/Total wage:** Share of managerial wage in total wage of a firm.
5. **Managerial incentives/Total incentives:** Share of incentives or bonuses in total incentives of a firm. Incentives is a sum of bonuses or perquisites, commission, contribution to pension, contribution to provident fund.
6. *HighTech:* It takes a value 1 if the average of R&D expenditure and royalty payments for technical knowhow (technology transfer) is greater than the median of the industry average, to which the firm belongs and zero otherwise.
7. *IPR₀₂:* It takes a value 1 if year is greater than equal to 2002.
8. **Horizontal Span of Control or Product Variety:** The number of different varieties of product produced by a firm.
9. **Vertical Layers or Management Layers:** The number of vertical layers – 1, 2 or 3. We assume a firm to have 2 layers throughout – one management layer and non-managerial layer.
10. **Capital employed:** Total amount of capital employed by a firm.
11. **Assets:** Total assets of a firm. It is an indicator of size.
12. **Age:** Age of a firm in years.
13. **Ownership:** It indicates whether a firm is domestic-owned or foreign-owned.
14. **Input/Output tariffs:** Input/output tariffs at the 4-digit industry level, obtained from Ahsan and Mitra (2014) for the period of 1990-2003, with the balance collected from Chakraborty and Raveh (2018).
15. $(ChM/TotalM)_{India}$: Share of Chinese imports in total imports of India. It is a measure of import competition.
16. $(InM/TotalM)_{US}$: Share of India's exports to the US. It is a measure of export market competition.
17. **Skill intensity:** The 3-digit industry level ratio of non-production workers to all employees, obtained from the Indian Annual Survey of Industries (2001-2006) and from Ghosh (2014) (1990-2000).
18. **Management Technology:** The 4-digit industry level management quality score in 2004, obtained from Bloom and Van Reenen (2010); the score is between 1 and 5, with 5 denoting the highest quality.
19. **Factories:** The 3-digit industry level number of factories/plants.

20. **Productivity:** Total Factor Productivity (TFP) at the firm-level is computed using the Levinsohn and Petrin (2003) methodology.

21. **Exporter/Non-Exporter:** It takes a value 1 if a firm's export earning is greater than zero and 0 otherwise.

22. **Intermediate/Final goods:** These goods are classified according to the I-O table by end-use. The intermediate goods category includes intermediates, capital and basic goods, whereas the final goods category includes consumer durable and consumer non-durables.

Industry FE (2-digit)*Year FE	No	Yes	No	No

Notes: Columns (1) - (2), (3) and (4) use total managerial compensation, middle managers compensation and top managers compensation of a firm, respectively as the dependent variable. ‘ IPR_{02} ’ is a dummy variable, which takes a value 1 if year is greater than equal to 2002. ‘ $HighTech$ ’ is a dummy variable which takes a value 1 if a firm’s expenditure on account of R&D Expenditure and Technology Transfer before the year 2001, is greater than the median of the industry, to which the firm belongs. ‘Capital Employed’ is the total amount of capital used by a firm at $t - 1$ period. Firm controls include age, age squared of a firm and assets of a firm. ‘Assets’ is used as the size indicator at $t - 1$ period. Both ‘Capital Employed’ and ‘Assets’ are expressed in their natural logarithmic form. Numbers in the parenthesis are robust clustered standard errors at the firm level. Intercepts are not reported. ^{c, b, a} denotes 10%, 5% and 1% level of significance, respectively.

Notes: Columns (1) - (5) use total number of non-managers, share of non-managerial compensation in total compensation, average non-managerial compensation, average non-managerial wages and average non-managerial incentives, respectively as the dependent variable. ' IPR_{02} ' is a dummy variable, which takes a value 1 if year is greater than equal to 2002. ' $HighTech$ ' is a dummy variable which takes a value 1 if a firm's expenditure on account of R&D Expenditure and Technology Transfer before the year 2001, is greater than the median of the industry, to which the firm belongs. 'Capital Employed' is the total amount of capital used by a firm at $t - 1$ period. Firm controls include age, age squared of a firm and assets of a firm. 'Assets' is used as the size indicator at $t - 1$ period. Both 'Capital Employed' and 'Assets' are expressed in their natural logarithmic form. Numbers in the parenthesis are robust clustered standard errors at the firm level. Intercepts are not reported. ^c, ^b, ^a denotes 10%, 5% and 1% level of significance, respectively.

Table 15: Intellectual Property Regimes and Firm Structure: Disaggregating the Compensation - Additional Results

	Managerial Wages/ Total Compensation			Managerial Incentives/ Total Compensation		
	All Managers (1)	Middle Managers (2)	Top Managers (3)	All Managers (4)	Middle Managers (5)	Top Managers (6)

Notes: Columns (1) - (3) and (4) - (6) use ratio of managerial wages to total compensation and ratio of managerial incentives to total compensation of a firm as the dependent variable, respectively. IPR_{02} is a dummy variable, which takes a value 1 if year is greater than equal to 2002. $HighTech$ is a dummy variable which takes a value 1 if a firm's expenditure on account of R&D Expenditure and Technology Transfer before the year 2001, is greater than the median of the industry, to which the firm belongs. 'Capital Employed' is the total amount of capital used by a firm at $t - 1$ period. Firm controls include age, age squared of a firm and assets of a firm. 'Assets' is used as the size indicator at $t - 1$ period. Both 'Capital Employed' and 'Assets' are expressed in their natural logarithmic form. Numbers in the parenthesis are robust clustered standard errors at the firm level. Intercepts are not reported. ^{c, b, a} denotes 10%, 5% and 1% level of significance, respectively.
